June 1974

Fuel Cycle For a Transient Reactor System

Gerhard Mara*

Introduction

In this paper reactor strategy considerations made by Häfele, Manne and Schikorr /1/, /2/ are extended. In papers /1/ and /2/, these authors gave a short review of the work on reactor strategies performed in the sixties, followed by a study on possible options for the future supply of energy. They took into account new functions of known reactor types and proposed one possible reactor strategy that is based on these functions. Special attention was paid to the timing problem. Both, an asymptotic solution to the long range phase and the conditions for the preceding transient phase of the energy problem were considered.

The purpose of this paper is an analysis of the nuclear fuel cycle in the transient phase: The material flows in the nuclear industry as well as the necessary separative work are calculated for the 66 year period under consideration.

* As of July 1974 at Westinghouse Nuclear Europe, Rue de Stalle 73, 1180 Brussels, Belgium.

Prepared for the Study Project on Energy Systems, The International Institute for Applied Systems Analysis, Laxenburg, Austria.

General Assumptions

The assumptions made for such a transient phase can be summarized as outlined in the cited paper:

- All increased demands for electric power will be met by LWR's for the next one or two decades.
- No Pu-recycling in LWR's. All Pu produced shall be used to establish the first core inventories of new FBR's.
- The FBR does not double any more. The rate of its increase is proportional to the increase of the installed LWR capacity. The breeding gain of FBR's is used for the supply of U233 to the THTR.
- The THTR can be installed proportionally to the FBR. It produces by virtue of its high temperature hydrogen.

The aim of the following investigations is to calculate the consumption of natural uranium, the demand for separative work and the quantity of depleted uranium as a function of time.

A flow chart of the proposed reactor population is given in Fig.1.

Time schedule

LWR's are built at a rate of 18GWe/y during the first 18 years followed by a period of constant LWR capacity with the FBR accounting for an increasing share of the nuclear energy supply. After a period of 40 years starting with the installation of the first LWR the capacity of nuclear industry is suggested to meet all the electrical power requirements. Now the

installation of FBR's continue at the same rate by replacing the LWR's until after an integral period of 58 years all LWR's are dismantled. At this very point the THTR capacity should be able to meet all the process heat requirements. Fig.2 shows the development of the reactor population in steps of three years. The methods of calculation and the used data have been established in discussion with Mr. McGrath, GfK Karlsruhe, and partially refer to /1/, /2/ and /3/.

LWR System

Assume:

- 1) average burnup is $33 \text{ GW}_{\text{th}} \text{ d/t}$ /McGrath/
- 2) efficiency is 34%
- 3) 2,6% enriched uranium is required for initial loading,
3.2% for replacement /McGrath/
- 4) conversion to plutonium is $0,17 \text{ t/GW}_{\text{e}} \text{ y}$ /1/
- 5) Np + Am + Cm content of elements is $0,696 \text{ kg/t}$ /McGrath/
(per ton of original fresh fuel)
- 6) Losses in fabrication and reprocessing are for both,
uranium and plutonium respectively 0,5% at each and total
1% /McGrath/.
- 7) The lifetime of the reactor is assumed to be 30 years.
Representing the increase of LWR capacity with time by a step
function with a period of 3 years results in an initial and final
step of 27 GWe at time $t=0$ and $t=18$ and 54GWe/y at $t=3,6, \dots$
(see Fig.2).

(a) annual replacement quantity for the first step:

$$27 \cdot \frac{1}{0,34} \text{ GW}_{\text{th}} * \frac{365 \text{ d/y}}{33 \text{ GW}_{\text{th}} \text{ d/t}} = 878 \text{ t/y}$$

(b) the ratio of UNat requirements for initial loading and annual replacement is 500:200 /1/. The demand of natural uranium for the production of 1t 2,6% U-235 is 5,092t and of 1t 3,2% U-235 6,392t.

Initial loading requirements for the first step

$$878 \cdot \frac{500}{5,092} : \frac{200}{6,392} = 2756 \text{ t}$$

(c) amount of fission products produced is:

$$27 \cdot \frac{1}{0,34} \text{ GW}_{\text{th}} \cdot \frac{365 \text{ d/y} \cdot 10^{-3} \text{ t/kg}}{0,95 \text{ GW}_{\text{th}} \text{ d/kg}} = 30,5 \text{ t}$$

use for calculations: 1gm fissions \approx 0,95 MW_{th} d

(d) Quantity of plutonium: 27GWe \cdot 0,17t/GWey = 4,6 t/y

(e) total amount of heavy metals out of reactor is:

$$(a) - (c) = 847,5 \text{ t/y}$$

(g) Uranium left in fuel elements must be (f)-(d)-(e)= 843t/y

(h) loss to waste in reprocessing are:

- 1) all fission products (c)
- 2) all Np + Am + Cm (e)
- 3) 0,5% of incoming plutonium quantity
- 4) 0,5% of incoming uranium quantity

However a return of the 1% enriched U-235 in the spent

fuel is not included in the present calculations.

(i) natural uranium demand for annual replacements

$$878 \cdot \frac{1}{0,995} \cdot \frac{e_o - e_t}{e_n - e_t} = 5643 \text{t/y} \quad 5643 \text{t/y}$$

$$e_o = 3,2\%, \quad e_t = 0,25\%, \quad e_n = 0,7115\%$$

(j) natural uranium demand for initial loading:

$$2756 \cdot \frac{1}{0,995} \cdot \frac{e_o - e_t}{e_n - e_t} = \quad 14\ 106 \text{t}$$

(k) production of tails:

$$\text{annual replacement: } 5643 - 878 = \quad 4\ 764 \text{t/y}$$

$$\text{initial loading} \quad 14106 - 2756 = \quad 11\ 350 \text{t}$$

(l) separative work

$$\text{for initial loading: } 230 \cdot 27 \cdot \frac{522}{500} = \quad 6\ 507 \text{t}$$

$$\text{for annual replacement: } 110 \cdot 27 \cdot \frac{209}{200} = \quad 3\ 105 \text{t/y}$$

$$522 = \frac{14\ 106}{27}; \quad 209 = \frac{5\ 643}{27}$$

The values 230 and 110 correspond to those given in /1/ for ore U_3O_8 requirements of 500t/GWe for the initial loading and 200t/GWey for the annual replacement.

The natural uranium demand for the LWR system, the production of tails and the associated separative work as a function of time is shown in Fig.4. The corresponding values are listed in Tab.1,2 and 4.

The time delays between ore demand and fuel loading have been taken into account (3 years).

FBR System

- Assume:
- 1) 90% of energy production in core + axial blanket
 - 2) Average burnup of core + axial blanket elements is 80.000 MW_{th} d/t
 - 3) Average portion of plutonium to total heavy metal content of fresh elements is 8%.
 - 4) Losses in fabrication and reprocessing are for both, uranium and plutonium respectively 0,5% at each, in total 1%.
 - 5) Np + Cm + Am content of elements is 1,5kg/t (per ton of original fresh fuel).
 - 6) Radial blanket conversion is 0,3t U₃O₈/GWe
 - 7) FBR core + axial blanket is self-supporting in plutonium with a 1% over supply to account for losses.

Installation schedule: an initial step of 27GWe, followed by six steps of 54GWe and two final steps of respectively 42 GWe and 30GWe match the increase of 18GWe/y (see Fig.2).

(a) initial loading requirements for core + axial blanket:

In pile inventory of plutonium is 2,5t/GWe /1/. According to assumption 3) the total initial heavy metal requirements for the first step are: $27 \cdot \frac{2,5}{0,08} = 844$ t
total amount of uranium is $844 - 844 \cdot 0,08 = 776$ t
 U_3O_8 requirements for initial loading are: $776 \cdot 1,005 = 780$ t

(b) fuel element quantity per year for core and axial blanket:

$$0,9 \cdot 27 \cdot \frac{1}{0,4} \text{ GW}_{\text{th}} \cdot \frac{365 \text{ d/y}}{80 \text{ GW}_{\text{th}} \text{ d/t}} = 277 \text{ t/y}$$

(c) total plutonium quantity per years: $0,08 \cdot 277 = 22,2 \text{ t/y}$

(d) total amount of U8 is : $277 - 22 = 255 \text{ t/y}$

(e) amounts of fission products produced is:

$$0,9 \cdot 27 \cdot \frac{1}{0,4} \text{ GW}_{\text{th}} \cdot \frac{365 \text{ d/y} \cdot 10^{-3} \text{ t/kg}}{0,95 \text{ GW}_{\text{th}} \text{ d/kg}} = 23 \text{ t/y}$$

(f) total amount of heavy metals out of reactor is:

$$(b) - (e) 254 \text{ t/y}$$

(g) total plutonium out of reactor must equal (c)+1%
to account for fabrication and reprocessing losses: $22,4 \text{ t/y}$

(h) total amount of Np + Am + Cm present in fuel
element equal $1,5 \text{ kg/t} \cdot 277 \text{ t/y} = 0,4 \text{ t/y}$

(i) U8 left in fuel elements must be: $(f) - (g) - (h) = 231 \text{ t/y}$

(j) annual U8 requirements for replacement are:

$$(d) \cdot 1,005 - (i) \cdot 0,995 = 26 \text{ t/y}$$

(k) initial loading requirements for radial blanket:

assume the following dimensions of core and blankets:

core: $D = 163 \text{ cm}$

$H = 100 \text{ cm}$

axial blanket: $D = 163 \text{ cm}$

$H = 2 \times 20 \text{ cm}$

radial blanket: $D_1 = 163 \text{ cm}, D_2 = 243 \text{ cm}$

$H = 100 + 2 \times 20 = 140 \text{ cm}$

The calculated ratio of volumes of core + axial blanket and of the radial blanket is 2,92 : 3,57. According to this ratio, the initial requirements of thorium for the first 27 GWe step could be calculated:

$$844 \cdot \frac{3,57}{2,92} = 1031 \text{t}$$

$$\text{at the fabrication facilities: } 1031 \cdot 1,005 = 1037 \text{t}$$

- (1) assuming a lifetime of 8 years for the radial blanket,
the annual replacement requirements are: $1031/8 = 129 \text{t/y}$
(m) amount of fission products produced in the radial
blanket is:

$$\frac{2,7}{0,4} \text{ GW}_{\text{th}} \cdot \frac{365 \text{d/y} \cdot 10^{-3} \text{t/kg}}{0,95 \text{GW}_{\text{th}} \text{d/kg}} = 2,6 \text{t/y}$$

- (n) quantity of U3 in radial blanket elements: $0,3 \cdot 27 = 8,1 \text{t/y}$
(o) total quantity of thorium remaining in radial blanket
elements:

$$(1) - (m) - (n) = 118 \text{t/y}$$

- (p) annual makeup thorium required at fabrication facility
for thorium radial blankets: $(e) \times 1,005 - (o) \times 0,995 = 12 \text{t/y}$
(q) quantity of U3 out of reprocessing facility to THTR:
 $0,995 \cdot 8,1 = 8,06 \text{t/y}$

The U8 and Th-requirements of the FBR system are shown in Fig.3 and the corresponding values are listed in table 2 and 3.

THTR System

Assume: 1) average burnup of elements is $95 \text{GW}_{\text{th}} \text{d/t}$
2) losses in fabrication and reprocessing are for
both, uranium and thorium respectively 0,5% at
each, in total 1%

3) Pa + Np content of spent fuel is 1,9kg/t
(fresh fuel)

4) conversion rate of THTR is sufficient to
balance U3 needs

The installation schedule is given in Fig.2. Since the annual fissile requirements are met by the FBR, the first THTR is installed 3 years after the first FBR in order to allow for reprocessing and fabrication delay. An initial step of 27 GWe at time 21 is followed by 12 steps of 54GWe and two final steps of 42GWe and 3GWe. This step function matches a steady increase of 18GWe/y of installed THTR capacity.

(a) annual replacement requirements:

8t heavy isotopes/GWe * 216t/y

(b) metric ton fissile purchased: 0,32 (U-235)*

metric ton fissile recycled: 0,19 (U-233)*

* These figures are given in a paper by Simcha Golan and R.Salmon /2/ and correspond to a 1000MWe HTGR and thorium fuel with U-235 makeup and U-233 recycle.

The neutron ratio of the two fissiles U-235 and U-233 is 2,05:2,28 and 0,32t U-235 + 0,19t U-233 are equivalent to $\frac{0,32 \cdot 2,05}{2,28} + 0,19 = 0,478$ t U-233 12,9t/y

(c) annual thorium replacement for the first step is:

27 (8-0,478) = 203t/y

(d) quantity of fission products produced:

$27 \cdot \frac{1}{0,4} \text{ GW}_{\text{th}} \cdot \frac{365 \text{ d/y} \cdot 10^{-3} \text{ t/kg}}{0,95 \text{ GW}_{\text{th}} \text{ d}} = 26 \text{ t/y}$

(e) total thorium content of spent fuel:

8.27t/y heavy isotopes - 25,95t/yFP - 0,19·27t/yU3-

-8·27·0,0019t/y(Pa+Np) = 185t/y

(f) annual demand for thorium is

$$(c) \cdot 1,005 - (e) \cdot 0,995 = \quad 21t/y$$

(g) initial loading requirements

$$\begin{array}{l} \text{heavy isotopes: } 35t/GWe \\ \text{fissile: } 2,025t/GWe \end{array} \quad) /2/ \quad 945t$$

$$U5(93\%) = 2,025/0,93 = 2,177t/GWe \quad 59t$$

$$(h) \text{initial thorium requirements: } 1,005 (945-58,78) = \quad 891t$$

(i) natural uranium requirements for initial loading:

$$540t/GWe /1/ \quad 14580t$$

$$(j) \text{tails are: } 540 - 540 \cdot \frac{0,7115-0,25}{93-0,25} = 540-2,687 = \quad 537,31t/GWe \quad 14507t$$

$$(k) \text{separative work for initial loading is } 438t/GWe /1/ \quad 11826t$$

The natural uranium, thorium and separative work requirements are shown in Fig.3 and 4. The corresponding values are listed in Tab.1, 2, 3 and 4.
