Energy for the Future

Evaluating different electricity-generation technologies against selected performance characteristics and stakeholder preferences: Insights from the case study in Jordan

International Institute for Applied Systems Analysis

The International Institute for Applied Systems Analysis (IIASA) is a non-governmental research organization supported by national academies of sciences from several countries in Africa, Asia, Europe, North and South America. IIASA conducts interdisciplinary scientific studies on environmental, economic, technological, and social issues in the context of human dimensions of global change.

The long-term aim of the IIASA Risk and Resilience (RISK) program is to conduct conceptual and applied analysis that contributes to decreasing the risk and vulnerability of societies and ecosystems and promoting their adaptation and resilience to stresses imposed or aggravated by global change phenomena. The RISK program has extensive experience in modeling, stakeholder interviews, participatory processes, and conflict resolution in many different risk contexts, most recently with respect to public resistance to energy transmission lines. RISK staff have pioneered stakeholder approaches based on the theory of multiple perspectives (also known as cultural theory).

The Governance in Transition Group within the RISK program is working with policymakers worldwide to find solutions to global and universal problems through applied systems analysis in order to improve human well-being in a variety of respects. The group has many years’ experience of how governance structures shape policy outcomes, having contributed to research on decisionmaking processes, public acceptance, risk perception, cognitive biases and cultural perspectives, as well as participatory governance design.
University of Jordan

The University of Jordan (UJ) is a public university, founded in 1962 by royal decree, located in the capital city of Amman. It is the Jordan’s largest and leading institution of higher education, and has evolved into a comprehensive university with national and international prominence. It has offered a wide choice of academic programs for students who can choose from more than 250 Programs from 24 schools in various disciplines.

UJ offers 94 bachelors in different programs in Medicine, Dentistry, Pharmacy, Nursing, Rehabilitation Science, Science, Agriculture, Engineering, Information Technology, Art, Business Administration, Sharia’a, Educational Sciences, law, Physical Education, Arts and Design, International Studies, Foreign Languages, Archaeology and Tourism. At graduate level, UJ provides 38 doctoral Programs, which represent more than 50% of doctoral programs in Jordan, and 111 master programs, which represent about 25% of master programs in Jordan, 16 higher specialization programs in medicine and one in dentistry, and 3 diploma programs.

Since its foundation, the number of UJ graduates has exceeded 200,000 graduates around the world, and UJ’s employment reputation is 330 worldwide according to QS World Universities Ranking.
Stockholm University

Stockholm University is a leading European university in one of the world’s most dynamic capitals. It sits in the middle of the world’s first National City Park, while the city centre is just a few minutes away. The blend of nature, historical surroundings and access to the job market, cultural events and entertainment makes the University unique. The University is characterised by its openness, innovation and collaboration. With a global perspective and through partnerships with others, it contributes to the global development of knowledge. Education and research within human/social sciences and natural science in the international frontline, as well as interdisciplinary work, make this possible. In an integral way, it makes knowledge accessible to everyone through dialogue and participation in public debate and the development of society.

The University was founded in 1878 with the ambition to reinvent higher education in Sweden. From the beginning, close contact with the surrounding society as well as the active exchange of knowledge and experience have been integral to this vision. For more than a century, an inherent quality culture has evolved at the universities; a continuous process of self-evaluation and mutual peer review – a unique academic culture. This culture, where traditional peer reviews are a cornerstone, is constantly protected and developed. Academic freedom is paramount to the University. In a changing and globalised world, the University contributes to a sustainable democratic society with a long-term vision, based on a solid scientific foundation that evolves constantly through the search for new knowledge.

In total, the University has over 55,000 students, 1,700 doctoral students and 5,000 employees. It is the home to the nation’s most substantial research within natural science and human/social sciences, as well as the home of a large number of internationally prominent research environments. Stockholm University is one of the higher-ranked universities in the world, such as position 74 on the Academic Ranking of World Universities, and one of the top 30-50 universities in Europe according to several well-established university ranking tables.
SUMMARY

Currently, energy policy in Jordan is facing a challenge of covering the country’s electricity demand which is growing because of different factors, among them the growing population, cooling, desalination, large consumption centres and industry. The goal to provide reliable and affordable electricity includes diversification of electricity-generation sources from extensive reliance on fossil fuel imports to the generation of electricity from locally available resources, such as renewable energy sources but also nuclear energy and shale oil.

Energy transition towards a more significant share of domestically generated resources will inevitably lead to a societal transformation in Jordan, which will affect interests of existing and emerging electricity-generation industries and other stakeholders. To be sustainable, such transition should also address issues of environmental protection and contribution to socio-economic development. Therefore, it is necessary to develop compromise solutions to mitigate the risk that differences in views about electricity generation technologies needed for energy transition will turn into conflicting opinions. Also, energy transition should address not only national energy security targets, but it should also integrate interests of local communities, where electricity-generation and transmission infrastructure will be located.

This deliverable is based on the assumption that human factors play an important role in energy transition. These human factors include perceptions of different risks connected with technological deployment as well as views about benefits and impacts generated by different technologies. An innovative methodology was developed to address these views. This methodology allows assessing the relevance of Jordan’s electricity-generation technologies, such as utility-scale photovoltaic (PV), concentrated solar power (CSP), onshore wind, utility-scale hydro-electric, bituminous coal, heavy fuel oil, shale oil, natural gas, against a set of criteria, which reflect environmental, social and economic components of sustainable development.

The results show that utility PV technology is the most preferable technology according to the stakeholders’ preferences. The results also show that currently the discourse in the Jordanian society is dominated by economic rationality, such as electricity costs, supported by concerns about safety during operation and maintenance of electricity-generation power plans. The results also show a strong desire of all stakeholders’ groups to have an opportunity for engagement into decision-making processes on energy transition, rather than to purely compensate local communities for the installation of electricity-generation and transmission technologies.

INTRODUCTION

The Hashemite Kingdom of Jordan is considering different options to satisfy its energy demand. Among these options are fossil fuels, such as coal, gas and oil, new fuels, such as shale oil, nuclear energy and renewable energy sources, such as wind and solar renewable energy sources. These technologies are needed to satisfy growing energy demand in Jordan. Projections show that energy demand in Jordan will be increasing during the next decades largely due to population growth, migration dynamics in the region, an increase in the quality of life as well as the increasing need for desalination of water and cooling due to climate change—both requiring large amounts of energy. For example, energy demand forecasts for Jordan show an annual increase in five per cent of Jordan’s primary energy demand and six per cent of Jordan’s electricity demand annually by the year 2020 (Komendantova et al., 2017).

The deployment of new technologies as well as higher use of existing technologies, which are needed to cover energy demand and to diversify energy supply, will lead to an energy transition in Jordan and a transformation of the Jordanian energy system. Energy transition in Jordan will be and already is a complex process, which has political, social, economic and technical dimensions. Therefore, a holistic, inclusive and comprehensive governance approach to energy transition is essential. The process of substituting one energy source by another, and of one technology by another can result in significant socio-technical changes which might lead to many frictions and conflicts. This process will not only lead to technological change, but it will also lead to a socio-technological transition process, which will be combined with shifts in generation and distribution technologies, business models, governance structures, consumption patterns, values and worldviews. For a sustainable implementation of this process, new forms of governance are needed.

Several works on energy transition in Jordan have dealt with economic and technological factors. Also, following national and international practice as well as the Jordanian political will, Jordan has been developing a legal and regulatory framework to attract investment into renewable energy expansion. There has been little debate, however, about the Jordanian society’s energy transition and transformation, which might result in the large-scale deployment of new technologies, and about the human factors and socio-economic consequences of this transformation of energy systems.

Energy transition in Jordan must be regarded as an arena where different individual or organized stakeholders are competing for legitimization of their actions and organizational settings for the future. Today, the energy field in Jordan is dominated by large providers, often owned by the public hand, which generate, transmit and distribute electricity to consumers. This field evolved
through a strictly favored centralized solutions. Often electricity providers, coal, oil and gas companies are regarded as incumbents, namely, actors who have disproportionate influence within the field. Their views and interests are also often reflected in the dominant organization of the strategic action field, which might be entirely shaped by the worldviews, interests and positions of these incumbents. New technologies, such as renewable energies, nuclear or oil shale, or governance modes, such as a more decentralized energy generation or participatory governance, can challenge the power distribution within this field. In this context, the process of learning from other regions and technology transfer, which goes beyond single projects, but includes regional models of energy transitions and transformation of society, should also cautiously be considered. There are several examples and good practices from Europe, such as the "Energiewende" (energy transition) in Germany or energy transition through climate and energy models in Austria. However, plans for energy transition in the MENA region should consider completely different energy market structures, stakeholder networks and societal aspirations towards energy, climate and environmental policies in the region (FES 2015). Therefore, careful consideration of stakeholders’ views, concerns and conflicting priorities is required when considering a sustainable energy transition and transformation of the energy system as well as for compromise-oriented energy governance solutions.
**BACKGROUND**

**Energy transition in Jordan**

Jordan is an energy importing country (around 97 per cent of its energy needs are covered by imported crude oil, natural gas and petroleum products). Renewable energy contributes only a minor share of Jordan’s electricity mix. Jordan also has plans for the use of other energy sources such as shale oil or nuclear power. The debate about large-scale deployment of renewable energy systems (RES) in Jordan, as well as in the entire MENA region, started with large-scale international projects such as DESERTEC and Mediterranean Solar Plan, even though single initiatives to deploy RES had already existed before. The DESERTEC concept was based on the idea of developing solar and wind projects in the MENA region and of generating electricity for exports to Europe via high voltage direct current cables (Czisch 2005). In response to this idea, a number of assessments were conducted to evaluate the technical and economic feasibility of such solutions (German AerospaceCenter, 2005, 2006; Ummel & Wheeler, 2008). The DESERTEC idea constituted the basis for the DESERTEC Industrial Initiative, which planned to stimulate €440 billion in investment into RES capacities in MENA. In 2008, the French government proposed the creation of the Union for the Mediterranean and the Mediterranean Solar Plan (MSP) as a starting initiative for this process. MSP had as a target to deploy 20 GW of solar capacity in the MENA region by 2020.

These incentives paved the way for technology transfer to the MENA region. However, they failed due to a variety of factors, amongst them social and public acceptance (Komendantova et al., 2017). Other reasons included the governance of this transition, which was based on a top-down framework of national renewable energy master plans elaborated by the MENA governments. The realization of these plans was far behind the settled targets, mainly, because energy transition roadmaps underestimated the intricacy of managing transformative change towards sustainable energy systems (Brand, 2015).

Being dependent on imported energy sources is a heavy burden for the socio-economic and energy security of Jordan. During the last decades, energy supply to Jordan was very volatile, not only because of volatility in prices for energy carriers but also because of a number of external political shocks and setbacks. For example, increasing prices of crude oil during the Arab Spring in Egypt significantly affected Jordan, which is dependent on energy imports from Egypt. The interruption of the Egyptian gas supply forced Jordan to switch to much more expensive heavy oil. This created a heavy burden for the Jordanian budget and increased significantly the already existing budget deficit. To cover for the difference between imported energy costs and its affordability on the local...
market, the Jordanian government had to heavily subsidize energy imports, which further increases its national deficit.

**Current situation in the energy sector in Jordan**

Due to the lack of energy resources, the question of how to cover energy demand is a constant challenge in Jordan. This country is heavily dependent on imports of energy, largely from fossil fuels. It, therefore, also suffers from the fluctuation of energy prices, which increases the Jordanian national debt and affects its national economy. According to the Ministry of Energy and Mineral resources (MEMR), Jordan imports over 95 per cent of its energy needs. This situation will become even more acute if the annual growth of primary energy demand of seven per cent is taken into account.

One of the crucial achievements in the Jordanian energy sector in 2017 was the completion of the Aqaba terminal in 2017. The goal of this project was to secure the supply of crude oil and oil products to Jordan. The terminal has storage capacities for crude oil, oil products and liquefied petroleum gas. The Logistic Company for Jordan’s Oil Facilities was established in the year 2016 as the operator and manager of this project. The costs of crude oil and oil products imports reached JOD 1.333 million in 2016. In general, the year 2016 witnessed a decrease of around 21 per cent in the consumption of oil products due to the decrease of demands for oil products used in electricity-generation and large imported quantities of natural gas.

The oil shale sector also experienced a significant development in that year. Jordanian decision-makers consider this energy source to be strategically important, considering the fact that Jordan has the fourth-largest oil shale reserve in the world, exceeding 70 billion tons. In 2017, the Jordanian government signed several memoranda of understanding and gave concessions for local and international companies to invest in the area of oil shale, including in-situ retorting and direct burning to generate electricity.

In 2017, the natural gas sector also experienced some development. The National Petroleum Company signed the production-sharing agreement with the IPG Company to develop the Risha field. Two liquefied natural gas (LNG) agreements were also signed between NEPCO and Shell International Company to expand the use of natural gas in power plants and industries.

In 2017, direct agreements were signed with the projects developers and the financing community for a rehabilitation project of the Al Hussein thermal station. It is expected that the commercial operation of the station will start in the second half of 2018.
In 2017, a memorandum of understanding was also signed between Jordan, represented by NEPCO, and the Gulf Cooperation Council Interconnection Authority GCC to initiate the preparation of technical and economic feasibility studies for electricity interconnections in the region.

Jordan has excellent potential sources of renewable energy, particularly solar and wind energy. In 2016, the installed capacity of conventional resources was 4.100 MW, while the installed capacity of renewables reached 544 MW. The renewables’ contribution to installed capacity is 13 per cent, and 5.6 per cent to generated electricity (MEMR, 2017). The Ministry of Energy and Mineral Resources has adopted an ambitious programme to increase the contribution of renewables to the total energy mix and to reach a 10 per cent share by 2020.

About 2.400 MW of wind and solar PV projects are expected to be developed in Jordan by 2020. In 2017, more than 625 MW were already operational. The share of solar and wind in 2017 reached 6.5 per cent of generated electricity. There are also 625 MW of wind and solar PV under construction. For these projects, MEMR follows a four-tracks-approach in developing renewables: the direct proposal scheme, the competitive bidding, the EPC turn-key projects and the small-scale renewable energy schemes (net metering) (MEMR, 2017).

In 2017, the green corridor project saw ongoing grid expansion and reinforcement plans and will continue as NEPCO is planning for it to contribute to the upgrading of the national grid capacity to assimilate 1.200 MW of renewable energy projects in the southern area of Jordan. It is expected that the project will be completed by the end of 2018 (NEPCO, 2015).
Participatory governance

Energy transition in Jordan is a complex process, which involves different views on risks and benefits of available and emerging electricity-generation technologies. This process is also changing the existing Jordanian energy mix, with some technologies losing their importance and other ones winning the market share. The use of new electricity-generation and transmission infrastructure also affects local communities with regard to water and land use as well as human health, air and the environment, in general. Such a complicated process requires a participatory approach to address existing differences in views and to develop compromise solutions.

Scientific evidence shows that the transformation of energy systems often faces risks and boundaries regarding the implementation of climate change mitigation policies, which are connected with decision-making processes (Patt, 2015). These boundaries include not only technological and economic factors but also human factors, such as conflicting views of risks and benefits of different technologies as well as social and public acceptance, willingness to use technology and to pay for it (Komendantova et al., 2018).

Today, public interest in energy infrastructure is different than it was half a century ago when the existing infrastructure was built. The existing energy infrastructure was perceived as a driver for socio-economic development. Nowadays, people want to participate in the decision-making process on technologies that affect their communities. Participation in decision-making processes is often perceived as a democratic principle of the inclusiveness of people (Beierle & Cayford, 2012). The lack of opportunity to exercise this right leads to protests, delays in the implementation of the projects and even the cancellation of projects because of public protests or actions of stakeholders who were not included in the decision-making process (Kunreuther et al., 1994).

International legislation also lays down the right to participate. The Aarhus Convention requires the involvement of stakeholders in decision-making processes on infrastructure projects and on providing clear and transparent information about how to get involved. However, often there are limits to participation; the fact that energy transition is a topic heavily dominated by technological and economic content hinders effective public participation (Devine-Wright, 2012). Jordan is not a party to the Aarhus Convention but we assume also expectations on participation in this country.

Different views on participatory governance exist. Some argue that complex decision-making process on critical infrastructures, such as energy, should be left in the hands of experts and scientists. Public participation is reserved as a method for evaluating this decision-making process and its outcomes (Rowe & Frewer, 2000). Others argue that participation is very beneficial because it
brings additional knowledge of stakeholders at the national level (Hänlein, 2015), which might be limited, such as the knowledge of local areas (Jasanoff, 1997). There is also evidence that to integrate views of all stakeholders—and not only those of specialized experts—can enhance the legitimacy of decision-making processes and build trust (Renn, 2008).

Evidence from energy generation and transmission projects in Europe shows that decision-making processes along the so-called “decide-announce-defend” (DAD) model, where the decision is taken by the national government, aided by experts and then implemented through a top-down approach, is no longer feasible (Wolfsink, 2000; Komendantova & Battaglini, 2016). The DAD model often leads to conflicting opinions as well as protests which delay implementation and may even lead to cancellation of the projects (Wolfsink, 2012).

Discussions in the framework the so-called Not-in-My-Backyard-(NIMBY) concept often end up simply identifying factors of acceptance, which is a more passive attitude towards a top-down decision-making process where someone cannot change anything. Nowadays many scientists argue that NIMBY is a misleading concept to understand local objections and concerns. One flaw of the concept is that it does not involve local knowledge to improve the results of decision-making processes (Batel & Dewine-Wright, 2015).

There is also the need to understand how engagement and participation can go beyond a discussion of the projects’ details and shape the discussion about centralized and decentralized energy transition as this is a complex topic where human factors play a significant role. Understanding is needed about how participatory governance works in different countries and how centralization or decentralization of decision-making shapes the process of stakeholders’ involvement in the discussion about energy transition issues (Komendantova et al., 2015).

Even though a significant part of existing literature on participatory governance research is focused on Europe, there is also evidence about advantages of a participatory approach for other countries. For instance, Xavier et al. (2017) studied implications of human factors on the transformation of the energy sector in South Africa. Having analyzed several infrastructure projects, the authors express the need to incorporate public participation within the project cycle and to institutionalize it as a part of the whole decision-making process. They also find that existing conflicts in stakeholders’ views and opinions can be mitigated through engagement and different methods of multi-criteria discussion.

Yazdanpanah et al. (2015) also looked at human factors of energy transition in Iran that influence the willingness to use renewable energy sources. By applying the theory of planned behaviour, the authors identified the main factors as moral
norms, attitudes and perceived behavioural control which is also connected with the possibility to influence decision-making processes.

**METHODOLOGY AND CRITERIA**

**MENA-SELECT methodology**

In the MENA-SELECT project, a set of criteria was developed which we are briefly describing. We compared technologies against a set of evaluation criteria and performance indicators. These criteria are important to understand how we obtained our results.

Each Jordanian technology, which is considered in the national energy planning, was evaluated against a set of criteria. Altogether, there were eleven criteria, which included 20 indicators, nine of which were quantitative, and 11 were qualitative. Data for quantitative indicators was collected from national and international statistical databases, reports and projects. Data for qualitative indicators were collected from surveys with stakeholders in Jordan.

We developed these criteria based on the review of scientific literature on energy generation and transmission technologies, as well as on the analysis of national policy documents for three relevant countries for MENA-SELECT (Morocco, Jordan and Tunisia).

All criteria were divided into two sets:

- **Contribution to national energy policy targets** such as to secure reliable and affordable power supply. It included such criteria as decreasing dependence on foreign resources, climate change mitigation, domestic industry development, technology and knowledge transfer, as well as affordable electricity system costs.

- **Sensitivity to local conditions and impacts on local communities.** They included aspects of land and water resources, on-site job creation, air pollution and health, hazardous waste and safety issues.

The project team selected eleven out of initially 32 relevant criteria. These were then discussed during the stakeholder workshops to see whether the stakeholders agree with the criteria definition, whether the criteria are relevant for the case countries and whether stakeholders would recommend any further criteria. The stakeholders' reactions confirmed the robustness of the selected criteria and their definitions that were also communicated to stakeholders during the workshops.

---

1 The criteria themselves including the methodology of their development and calculation are described in more detail in Schinke et al. (2017).
MENA-SELECT criteria

**Criterion 1: Use of domestic energy sources.** The dependence on foreign energy imports can be decreased by tapping into domestic resources that are either available today or could be exploited in the mid- to long-term. Two indicators are relevant here: a) Current domestic potential of each technology's energy carrier to decrease energy import dependence today, and b) Future domestic potential of each technology's energy carrier to decrease energy import dependence by 2040/50.

**Criterion 2: Global warming potential.** The technology should contribute to the mitigation of climate change. The criterion is based on the indicator “Total lifecycle GHG emissions (CO2-eq) per generated kWh”.

**Criterion 3: Domestic value chain.** The technology should have a high potential to use components and services provided by domestic industries throughout the entire value chain. The criterion is based on the indicator “Existing potential for the integration of domestic industries to manufacture a significant share of components and provide essential services during the Manufacturing, Construction and Installation (MCI) and Operation and Maintenance (OM) phases of the technology”.

**Criterion 4: Technology and knowledge transfer.** Based on existing policies, the technology should have a high potential to benefit from technology and knowledge transfer to stimulate future domestic value added in electricity-generation. The criterion is based on the indicators a) Effectiveness of educational policies to foster skill development and R&D, and b) Effectiveness of industrial policies to enhance industry linkages between domestic and foreign firms geared towards horizontal technology transfer.

**Criterion 5: Electricity system cost.** The electricity system cost of the technology should be as low as possible as not to constitute a burden for Jordan’s overall budget. The criterion is based on the indicators a) Electricity-generation cost measured as Levelized Cost of Electricity (LCOE) in €/MWh, and b) Estimated additional integration cost at increasing penetration levels based on uncertainty/variability and distance/location.

**Criterion 6: On–site job creation.** The technology should have a high potential to create direct on-site jobs over the entire lifetime of the power plant. The criterion is based on the indicators a) MCI: Average amount of labour in FTE person-years per MW, and b) OM: Average amount of labour in FTE permanent jobs per MW.

**Criterion 7: Pressure on local land resources.** The technology should cause minimal additional pressure on valuable land resources regarding amount and value of required land to avoid the deprivation of any locally relevant livelihood.
resources. The criterion is based on the indicators a) Land requirement: The area of land directly required by the technology at the site of its deployment in ha/MW, and b) Land value: The importance of the land surrounding typical project sites for providing livelihood resources and services to adjacent communities.

**Criterion 8: Pressure on local water security.** The technology’s water consumption should be appropriate to the local water risk context and cause minimal pressure on local water security. The criterion is based on the indicators a) Average operational water consumption of each technology measured in L/MWh, and b) Average water risk at typical project sites of each technology based on the Water Risk index of WRI (2014).

**Criterion 9: Occurrence and manageability of non-emission hazardous waste.** The disposal of non-emission hazardous waste produced during the operation of the technology as well as the risk stemming from national waste management capabilities should be low to minimize adverse consequences on human health and the environment. The criterion is based on indicators a) Disposal of non-emission hazardous waste, and b) Potential national capabilities to manage the disposal of the respective types of non-emission hazardous waste.

**Criterion 10: Local air pollution and health.** The amount of air pollutants (NOx, SO2 and PM) emitted by the technology should be low to minimize pressure on local air quality and health risks for people in adjacent communities. The criterion is based on the indicators a) Air pollutants (SO2, NOx, and PM$_{2.5}$) emitted by O&M activities of power plants in kt/MWh, and b) Premature deaths by PM$_{2.5}$/MWh of electricity produced.

**Criterion 11: Safety.** Severe accidents from the construction, operation and maintenance of electricity-generating technologies, as well as during the transport and storage of resources and equipment, should be minimized to reduce accidents resulting in fatalities within and outside power plants. The criterion is based on the indicators a) Historical immediate fatalities from severe accidents during transport and storage of resources and equipment, and operation and maintenance activities of power plants, per unit of electricity (MWh) produced (hereafter referred to as “normalized fatalities”), and b) Potential of regulatory and operational emergency preparedness and response capabilities of the private and public sector to mitigate and manage the risk of catastrophic accidents with maximum and severe consequences during the construction and operation phase of each technology (hereafter referred to as “normalized fatalities”).
Workshops to discuss criteria and visions

The workshops with stakeholders lasted the entire day and included several sessions. The first session started with the introduction during which the organizers presented the workshop and its objectives as well as the goals of the workshops and the agenda. The participants introduced themselves and their organizations.

![Moderator explains the methodology. Source: Nadejda Komendantova, IIASA](image1)

During the second session, the visions for Jordan and in the years 2040 and 2050 were discussed. Participants had an opportunity to describe how they see environmental, social and economic aspects of the future of Jordan. Then they wrote their choices on the different coloured cards and put them on a flipchart. Furthermore, they explained their choices.

![Participants discussing the economic, social and environmental future of Jordan. Source: Ahmed Al Salaymeh, University of Jordan](image2)

During the third session, the technologies were discussed. It started with a presentation of electricity-generation technologies relevant for Jordan and was followed by a discussion of positive and negative sides of each technology.
Participants also had a chance to suggest further technologies, which were not originally included in the list of discussed technologies.

The fourth session focused on the discussion of criteria. First, the criteria and their definitions were presented to the participants. Each criterion was discussed to make sure that participants understand its definition. Participants also had a chance to provide suggestions on how the definition of criteria could be changed and to add further criteria.

The fifth session was on criteria ranking during silent negotiation, which is a tool for collective ranking but in silence by avoiding any discussion (Pictet and Bollinger). The following rules applied to the session: At the beginning, the set of cards was displaced on the table in a random order. Then the moderator explained the ranking and the rules and asked participants to order cards in three rounds of silent negotiations. The three rounds were followed by a discussion to identify lines of conflicting opinions. During the first three rounds, participants made eight moves during the first round, five moves during the second round, three moves during the third round and finally, after the open
discussion, two moves in the fourth and final round. The order how participants were putting the cards was identified by the lottery.

The sixth session was on silent negotiation and white cards. The moderator introduced the blank cards and explained that they show the relative difference in importance for different criteria. The greater the difference in importance between two criteria, the more blank cards should be positioned in-between these criteria. (See Chapter 3.4 for a detailed description of the methodology.) Altogether, there were three rounds of silent negotiations. The first round had three moves, the second one had two moves and was followed by the open discussion. The final round had one move.

In the seventh session, the participants discussed procedural and output justice. This discussion focused on the following questions:
Access to information: How high is the need for information about the different energy technologies?

Meaningful participation in decision-making: How high is the need for participation concerning the different energy technologies?

Benefit sharing: How high is the need to share a reasonable amount of benefits with local communities?

Compensation of adverse impacts: How high is the need to claim the right to compensation?

To discuss these questions, the participants formed two groups and tried to reach a compromise on grouping four criteria in a ranking according to what they believed was important. Later, the results of the ranking were discussed, and participants provided their arguments why they found some criteria to be more important than others.

Three months later, we organized the final workshop to rank the criteria again and to discuss the results. We selected two most active participants from each stakeholders group. The procedure during the workshops was similar to that during workshops with homogenous groups of stakeholders, except that we did not have discussions about visions and technologies for Jordan. We rather had two rounds of rankings when participants had a chance to see and discuss our results between the rankings and then rank the criteria again. Participants from each stakeholder group also had to explain to other participants the reasons why their stakeholders groups decided in favour of this particular final ranking.
The stakeholder groups

Six groups of different stakeholders were involved in the MENA-SELECT workshops. These groups represent the most relevant stakeholders for energy policy in Jordan, which are: “policymakers”, “finance and industry”, “academia”, “young leaders”, “national and local NGOs” as well as “civil society” and “local communities”. These groups include the following stakeholders who participated different events of stakeholders dialogue organized in frames of the MENA-SELECT project such as workshops and surveys.

Policymakers:

This group represents decision-makers in the Jordanian government and representatives of relevant organizations, which are responsible for developing and implementing energy policy in Jordan. The participants were from the Ministry of Energy and Mineral Resources (MEMR), the Ministry of Water and Irrigation (MWI), the Amman Chamber of Industry, the Ministry of Public Works, the National Electric Power Company (NEPCO) and the Jordan Press Foundation/ Business section.

The Ministry of Energy and Mineral Resources (MEMR) is the overarching legislative authority on energy-related issues in Jordan and, as such, lays down the goals and political framework conditions for the development of the energy market.
The Ministry of Water and Irrigation (MWI) is responsible for the implementation of the Energy Efficiency and Renewable Energy Policy for the Jordanian water sector by rehabilitating different systems, installing new systems and renewable energy projects that include different programmes such as solar energy systems for administrative buildings of the water sector, the utilization of hydropower potential to power the water sector, the utilization of biofuel potential in wastewater facilities, and large-scale renewable energy-based power-generation for the water sector on available lands (MWI, 2015).

The National Electric Power Company (NEPCO) is responsible for the construction, planning, development, operation, maintenance and management of the control systems, the electric transmission and interconnection networks as well as for managing the processes of purchasing, transmitting, control and selling the electric power in Jordan and to the neighbouring countries. It also conducts the planning studies in this regard. The company provides services, consultancy and studies related to electric power to various parties inside and outside Jordan.

The Amman Chamber of Industry (ACI) is a non-profit organization which represents the industrial sector in Jordan. The ACI forms and develops a framework to crystallize the industrial point of view of its members in economic issues in general and industrial issues, in particular. To this effect, the chamber cooperates with the ministries and relevant government economic planning, especially with regard to industry, in coordination with the Jordan Chamber of Industry. Within the framework of ACI’s strategy and plans, it aims to promote the use of renewable energy and reduce energy costs for the factories.

The Ministry of Public Works and Housing (MPWH) is aiming to provide new governmental buildings that are environmentally friendly and energy-saving.

The Jordan Press Foundation is the owner of the Al Rai newspaper and is a shareholding company responsible for media coverage.

Finance and industry

The participants of this group represented energy and environment companies, engineering companies, banks and factories represented by the following companies: Greenviro for renewable energy, control and communication, Al-Masar Engineering Company, Arab Bank, Greenplans Environmental Consult, Petra Elevators Company and Qatrana Cement company.
The Banks in Jordan are involved in energy projects through signed agreements with The Jordan Renewable Energy and Energy Efficiency Fund (JREEEF) to finance renewable energy projects.

Jordan's industrial sector is composed mainly of the "mining and quarrying" and "manufacturing" subsectors. Large-scale industries operate primarily in the field of phosphate and potash mining, the industrial production of cement, fertilizers and refined petroleum. The industrial sector's energy consumption represented about 16 per cent of the total consumed energy in Jordan in 2016 (MEMR, 2016).

Al-Masar Engineering is a company specialized in the design and implementation of solar energy systems to generate electricity, store system electricity in batteries or connect them to the network. Al Masar Engineering is one of the first companies to use energy-saving heating pumps to heat water for home use.

GREENVIRO is a Jordan-based company that was established in 2013. The company offers customized energy consumption consultations, energy-saving system designs, energy-saving products as well as the design and installation of solar energy systems.

Control and Communications Company (CCC) was established in 1990. It provides the markets with industrial control systems, file tracking, access control, time attendance, fire alarms and other systems that could be used in the field of renewable energy systems.
Greenplans Environmental Consultations Ltd. Co. is an engineering consulting firm specializing in the environmental engineering and consulting services that cover the areas of water, environment, waste and energy (renewable energies and energy efficiency) related to engineering and environmental projects, industries, facilities and development zones.

Petra Elevators is a company that provides and designs an innovative range of elevators, lifts and other technical devices for smooth riding comfort, preciseness and reliable speed control.

The Qatrana Cement Company was established in 2007 with a total investment of 500 million US dollars. Qatrana cement plant is located 80 km south of Amman. A 30-megawatt power plant, which runs on coal, will be constructed to supply energy to the Al Manaseer’s cement factory in Qatraneh. It is planned that the project will be operational by 2025.

Academia
This group represents researchers and academics in the field of energy. The participants were faculty members and researchers from the University of Jordan, the King Abdullah II Design and Development Bureau (KADDB), Al-Zaytoona University, Applied Science University and the German Jordanian University. For example, the King Abdullah II Design and Development Bureau (KADDB) is an independent government entity within the Jordanian Armed Forces (JAF) aiming at becoming a global defence and security research and development hub in the region. The Bureau’s scope of work includes defence design and development, test and evaluation, technology incubation in the Kingdom and defence technology training.
The **University of Jordan** is a public university located in Amman. It is Jordan's largest and leading institution of higher education.

The **Al-Zaytoona University** is a private university and includes six faculties, encompassing 19 undergraduate specializations and one graduate programme.

The **Applied Science University** is a private university located in Amman, Jordan. It was established in 1991 as the largest private university in Jordan in terms of campus area and number of students' enrollment.

The **German Jordanian University** is a public university in Madaba, Jordan. It offers more than 20 programmes to about 5,000 students, primarily from Jordan. The University was modelled on the German applied-sciences model, characterized by their focus on putting knowledge into practice and on promoting knowledge transfer. It aims to play a significant role in promoting links between Jordan and Europe, particularly Germany. By taking advantage of the best educational practices in both Jordan and Germany, the University has positioned itself as a leader in its field.

**Young leaders**

This group represents the graduate students in the field of energy as well as young employees at energy and engineering companies such as Green Essence, KEPCO KPS IPP3 power plant and Gereenviro.

![Picture 1: Participants of the stakeholders group of young leaders/future decision-makers. Source: Leena Marashdeh, University of Jordan](image)

Green Essence specializes in renewable energy systems and is an authorized dealer for Suntech, the global leading PV panels manufacturer ranked as the
largest manufacturer in the world. It can be compared to the leading German
inverters manufacturer such as SMA.

KEPCO KPS IPP3 power plant is located on a green field site at Al Manakher,
30km from the Jordanian capital Amman. It is the world’s biggest tri-fuel power
plant with an installed capacity of 573MW. The plant is designed to use natural
gas and heavy fuel oil (HFO) as its main fuels and light fuel oil (HFO) as the back-
up fuel.

Civil society and NGOs

This group of stakeholders represents the national non-governmental
organizations in the field of energy, environment and engineering. The
participants were from the Energy Services Center, the Renewable Energy
Establishments Society, the Jordan engineer association (JEA), the Jordan
Environment Society (JES), the Jordan energy chapter and the Sanibel Society for
the environment.

![Participants of the stakeholders group of local communities and NGOs.](image)

Source: Jomana Tanbour, University of Jordan

The Center for Energy Services is an integrated centre for energy, renewable
energy and energy efficiency sector. It provides a range of training and advisory
services by a qualified team to build the capacities in this sector.

The Jordanian Engineers Association is a trade union of engineers in Jordan,
and it is the largest trade union in the country.

The Jordan Environment Society (JES) was established in 1988 as a non-profit
non-governmental organization. It is the largest NGO in Jordan in its field. The
objective of JES includes, but is not limited to, protect the environment and its basic elements such as water, air, soil and wildlife.

The Jordan Energy Chapter is partnered with the American Energy Engineers Association, which is a non-profit professional society of over 18,000 members in more than 100 countries. The mission of AEE is “to promote the scientific and educational interests of those engaged in the energy industry and to foster action for sustainable development”.

The Sanibel Society for the Environment is a non-profit organization concerned with environmental protection.

Local communities

This group represents the local community from different cities in north and south Jordan. The participants were employees from the Ministry of Municipal Affairs in Alsalt city, Madaba city and Zarqa city and interested citizens from Amman and Madaba.

The large-scale power-generating projects such as the Hussein Thermal Power Station and the first nuclear power plant are under development and construction in Zarqa City community. The cities of Amman, Alsalt and Madaba host a number of small and large-scale renewable energy projects.

The following workshops with different groups of stakeholders took place:

\ Group 1: Civil society and NGOs on 7 November 2016
Group 2: Finance and investment on 9 November 2016
Group 3: Academia on 10 November 2016
Group 4: future decision makers on 12 November 2016
Group 5: Local communities on 13 November 2016
Political decision-makers on 15 November 2016
Final workshop with mixed groups of stakeholders on 28 February 2017.

The following organizations participated in the workshops:

**Academia:** Al Balqa Applied University, Mutah University, University of Jordan, Applied Science University, German Jordanian University, American University.

**Local communities:** Greater Amman Municipality, Salt community, Ministry of municipal affairs, Municipality of Al Zarqa, Municipality of Madaba.

**Civil society and NGOs:** Energy Services center, Renewable Energy Establishments Society, Jordan engineer association, Jordan Environment Society (JES), EDAMA, Sanibel Society for Environment, Jordan press foundation.

**Private sector:** Arab bank, Gereenviro for renewable energy, Control and communication company, Al-Masar engineering company, Green plans consult, Qatrana Cement, NEPCO.

### Criteria ranking

One of the problems with most models for criteria ranking is that numerically precise information is seldom available, and most decision-makers experience difficulties with entering realistic information when they analyze the challenges of decision-making. For instance, Barron & Barrett (1996b) argue that the elicitation of exact weights demands an unreasonable exactness which does not exist. There are other problems, such as that ratio weight procedures are difficult to accurately employ due to response errors (Jia et al., 1998). The general lack of reasonably complete information increases this problem significantly. Several attempts have been made to resolve this issue. Methods allowing for less demanding ways of ordering the criteria, such as ordinal rankings or interval approaches for determining criteria weights and values of alternatives, have been suggested, but the evaluation of these models is sometimes quite complicated and difficult for decision-makers to accept.

The utilisation of ordinal or imprecise importance information to determine criteria weights is a way of handling this, and some authors have suggested surrogate weights as representative numbers assumed to represent the most
likely interpretation of the preferences expressed by a decision-maker or a group of decision-makers. The idea is to enable decision-makers to utilise the information they can supply and then generate representative weights from some underlying distribution and investigate how well they perform. One such type is derived from ordinal importance information (Barron & Barrett, 1996ab; Katsikopoulos & Fasolo, 2006), where decision-makers supply ordinal information on importance, and the information is then subsequently converted into surrogate weights corresponding to and consistent with the extracted ordinal information. Often, rank sum (RS) weights, rank reciprocal (RR) weights (Stillwell et al., 1981) and centroid (ROC) weights (Barron, 1992) are used.

Still the problem there is to elicit stakeholder information. Different elicitation formalisms have been proposed by which a decision-maker can express preferences. Such formalisms are sometimes based on scoring points, as in point allocation (PA) or direct rating (DR) methods. In PA, the decision-maker is given a point sum, e.g. 100, which they distribute among the criteria. Sometimes, it is pictured as putty with the total mass of 100 being divided and put on the criteria. The more mass, the larger weight on a criterion, the more important it is. When the first N–1 criteria have received their weights, the last criterion’s weight is automatically determined as the remaining mass. Thus, in PA, there is N–1 degrees of freedom (DoF) for N criteria. DR, on the other hand, puts no limit on the total number of points to be allocated. The decision-maker allocates as many points as desired to each criterion. The points are subsequently normalized by dividing by the sum of points allocated. When the first N–1 criteria have received their weights, the last criterion’s weight still has to be assigned by the decision-maker. Thus, in DR, there are N degrees of freedom for N criteria. Regardless of elicitation method, the assumption is that all elicitation is made relative to a weight distribution held by the decision-maker.

Simos proposed a simple procedure, using a set of cards, trying to indirectly determine numerical values for criteria weights (Simos, 1990ab). The Simos method is, however, a bit different from the methods discussed above. It is a relatively simple method for easily expressing criteria hierarchies while introducing some cardinality if needed. It has been widely applied and has been well-received by real decision-makers. When this method is used, a group of decision-makers are provided with a set of coloured cards with the criteria names written on them. They are also given a set of blank cards. Then, they are asked to rank, the coloured cards from the least important to the most important, where criteria of equal importance are grouped together. Furthermore, the decision-makers are asked to place the blank cards in-between the coloured cards to express preference strengths. Then, the surrogate numbers can be computed. A constant value difference, ‘u’, between two consecutive cards is assumed here. A blank card between two consecutive coloured cards signifies a difference of 2∙u, and two white cards represent a difference of 3∙u, etc.
However, one problem with the Simos method is that it is not robust when the preferences are changed (Scharlig, 1996) and that it has some other contra-intuitive features, such as that it only picks one of the weight vectors satisfying the model, while there can, of course, be an infinite number of them.

Furthermore, because the weights are determined differently depending on the number of cards in the subsets of equally ranked cards, the differences between the weights also change in an uncontrolled way when the cards are reordered. This is why (Figueira & Roy, 2002) suggested a revised version, where there is a more robust proportionality when these blank cards are used. It is accomplished by requesting the decision-makers to state how many times more important the most important criterion or criteria group is—compared to the least important. This addition seemingly solves some problems but introduces the complication that the decision-maker has to reliably and correctly estimate a proportional factor \( z \) between the largest and the smallest criteria weights.

We, therefore, used a variant of the Simos method for elicitation purposes and kept the card ranking part while changing the evaluation significantly compared to the Simos method and its revisions. At that point, the participants already knew the criteria well from the previous sections of the workshops. The key challenge in our workshops was to elicit a collective ranking. Most methods for ranking and weighting deal with individuals, we had to do it as a group effort. This was the main reason to opt for the card-ranking through a silent negotiation, not the calculation behind it.

Each criterion was written on a coloured card and arranged horizontally on a table. Then each of the participants successively ranked the cards from the least important to the most important by moving the cards to a vertical arrangement, where the highest-ranked criterion was put on top and so forth. If two criteria were considered to be of equal importance, they were put on the same level. This process went on for four rounds, where the number of moves for each round was 8, 5, 3 and 2. Furthermore, the first and third round was concluded by an open discussion before the following round. The ranking procedure lasted 120 minutes or until a final ranking was achieved that the participants found acceptable.

It is true that the decreasing number can be disputed and is a weak point of the method since it induces / forces the participants to act strategically in relation to the information they got during the process. So when this method is used, the potential conflicts must come to the open and be dealt with. In some cases, by working with a set of final ranking in the evaluations, where it turns out whether the differences are of importance or not. After the first ordinal ranking was finalized, the participants were asked to introduce preference strengths in the ranking by introducing the blank cards during three additional rounds (with three, two and one move). The number of white cards (i.e. The strength of the rankings between criteria) was also interpreted verbally:
The final rankings of the six workshops were handed to the representatives of each stakeholder group during the final workshop after two months, where the exercise was repeated for also with this group. They could then present each ranking and its rationales to the other participants during an introductory presentation round.

### Methods of analysis

A common approach to solve decision problems with multiple criteria is to specify a set of criteria that represent the relevant aspects of a problem, and then define a weight function over the criteria set. Value functions are then defined over the alternatives for each attribute. Common here is to use a weight function over the attribute set using fixed numbers on a normalised scale. The criteria weights thus describe each criterion’s significance in the specific decision context. Value functions over the alternatives are defined in a similar way. Thereafter, the overall score of each alternative is calculated by aggregating the various components.

One of the central issues of these methods is how to assign weights while avoiding too much information loss as well as preserving correctness in the weight assessments. Using criteria ordinal rankings usually avoid some elicitation difficulties that appear when limited to precise numbers only. Techniques for ordinal rankings are, however, quite different regarding their accuracy and decision-makers usually also have useable knowledge of decision situations than expressed in criteria orderings, c.f. e.g., (Danielson and Ekenberg, 2017b); information that should be used as well. The, so called, surrogate weights based on an ordering only may thus be too weak a representation. In the analyses, we have therefore included information regarding relational strengths.

Before, going into the evaluations, we will explain the issues with eliciting and representing preference orderings into some more details. A commonly used
class of methods here is the SMART family. These were quite early suggested as methods for weight assessment from criteria rankings, cf., e.g., (Edwards 1971, 1977). The basic idea is quite simple. Given a ranking, ten points are assigned to the weight of the least important criterion \( w_N \), whereafter the weights \( w_{N-1} \) through \( w_1 \) are given points according to the decision-makers’ preferences. The overall value, \( E(a_j) \), is then a weighted average of the values \( v_{ij} \) associated with alternative \( a_j \) (Eq. 1) under the criterion \( c_i \):

\[
E(a_j) = \frac{\sum_{i=1}^{N} w_i v_{ij}}{\sum_{i=1}^{N} w_i}
\]

Some years later, Edwards and Barron (1994) suggested the SMARTER method, and included an elicitation component for ordinal information before converting this to numbers. First, the weights are ordered as \( w_1 > w_2 > ... > w_N \) and are then transformed to numerical weights using ROC weights (see below), and then SMARTER continues as the ordinary SMART method.

The Analytic Hierarchy Process (AHP) is a well-known ratio scoring method (Saaty, 1977, 1980), where a set of alternatives are evaluated under a criteria tree by pairwise comparisons. For each criterion, the decision-makers assess the ordering of the alternatives. Thereafter, they assess the strength of the ordering by quite roughly considering ratios between the alternatives.

There are however some several shortcomings of these methods, and we have in a series of articles suggested a set of alternatives. A promising candidate to these methods is the Cardinal Ranking (CAR) method and we have shown that it is a more robust and efficient than the ones from the SMART family, AHP and many others.\(^3\)

We will use CAR, in the analytical part of this report, when translating the rankings to surrogate weights and subsequently use these values in the Multi-Attribute Decision Making (MADM) software DecideIT, which is designed for solving these types of problems under uncertainty.

**Calculations of surrogate weights from the ranking**

The CAR method of (Danielson & Ekenberg, 2016) converts the cardinal criteria ranking including the blank cards into numerical weights, while thereby limiting information loss. The idea is the following:\(^4\)

---

\(^2\) Simple Multi-Attribute Rating Technique

\(^3\) See, e.g., Danielsson & Ekenberg, 2016

\(^4\) This is more described in more details in (Danielson & Ekenberg, 2015, 2016)
1. Assign an ordinal number to each importance scale position, starting with the most important position as number 1.

2. Let the total number of importance scale positions be Q. Each criterion i has the position \( p(i) \in \{1, \ldots, Q\} \) on this importance scale, such that for every two adjacent criteria \( c_i \) and \( c_{i+1} \), whenever \( c_i > c_{i+1} \), \( s_i = | p(i+1) - p(i) | \). The position \( p(i) \) then denotes the importance as stated by the decision-maker. Thus, \( Q \) is equal to \( \sum s_i + 1 \), where \( i = 1, \ldots, N-1 \) for \( N \) criteria.

3. Use a reliable transformation algorithm for the generation of surrogate weights.

To find a such, we have some alternatives. For instance, consider the counterpart to RS weights (Barron, 1992). The concept of cardinal rank sum (CRS) weights is based on the idea that the rank order strength should be reflected directly in the weights. Then the CRS weights are obtained by Eq. 2

\[
w_i^{\text{CRS}} = \frac{Q + 1 - p(i)}{\sum_{j=1}^{N} (Q + 1 - p(j))} \tag{2}
\]

based on the importance positions \( p(i) \) as stated by the decision-maker. The counterpart to ordinal rank reciprocal weights is analogously defined.

According to step 2, let the total number of importance scale positions be \( Q \). Each criterion i has the position \( p(i) \) on the importance scale such that \( p(i) \leq p(j) \) if \( i < j \). Then the corresponding rank reciprocal (CRR) weights are obtained by Eq. 3

\[
w_i^{\text{CRR}} = \frac{1}{\sum_{j=1}^{N} (p(j))} \tag{3}
\]

with the usual property that a higher weight is assigned to lower ranking numbers. ROC weights (Danielson et al., 2014) are generalized in the same way. The ordinal ROC weights, given by Eq. 4

\[
w_i^{\text{ROC}} = \frac{1}{N} \sum_{j=i}^{N} \frac{1}{j} \tag{4}
\]

could be interpreted as candidate weights for positions on the importance scale. Then, the corresponding preference strength rank order centroid weights (CRC, Eq. 5) are

\[
w_i^{\text{CRC}} = \frac{\sum_{j=p(i)}^{Q} \frac{1}{j}}{\sum_{j=1}^{Q} (\sum_{k=p(j)}^{Q} \frac{1}{k})} \tag{5}
\]

---

5 Stillwell et al, 1981
Finally, the SR weights (Danielson & Ekenberg, 2014) are generalized in the same way. The ordinal SR weights are given by the Eq. 6

$$w_{i}^{SR} = \frac{\sum_{j=1}^{N} w_{j}^{'}}{\sum_{j=1}^{N} w_{j}^{'}}$$  \hspace{1cm} (6)$$

and the corresponding preference strength SR weights (CSR, Eq. 7)

$$w_{i}^{CSR} = \frac{\sum_{j=1}^{N} \frac{q+1-p(i)}{q} \frac{1}{p(i)}}{\sum_{j=1}^{N} \left( \frac{1}{p(j)} \frac{q+1-p(j)}{q} \right)}$$  \hspace{1cm} (7)$$

is a similar generalization as the other weights.

Ordinal weight methods are thereby easily generalized to their respective counterparts and we demonstrate in (Danielson and Ekenberg 2017a) that CSR should be preferred to the other candidates. This is also the evaluation method for the criteria ranking component used in CAR.

Now we turn our attention to the general evaluation of the entire decision problem.

Multi-Criteria Decision Analysis (MCDA)

Typically, a multi-criteria decision situation is modelled like a tree, such in the figure below, where the $w$:s are criteria weights and the $v$:s are values of alternatives under the different criteria.

![Figure 1: A multi-criteria tree](image)

The normalisation constraint means that the weights are restricted by the equation $\sum w_{j} = 1$, where $w_{j}$ denotes the weight of a criterion $G_{j}$ and the weight of sub-criterion $G_{jk}$ is denoted by $w_{jk}$. Denote the value of alternative $a_{i}$ under sub-criterion $G_{jk}$ by $v_{ijk}$.

A common value function for evaluating alternatives in the analyses is a weighted average of the components involved. For instance, consider an
alternative \( A_i \) under two criteria, with the respective weights \( w_1 \) and \( w_2 \). The overall value of this alternative can be calculated by a weighted average:

\[
E(A_i) = \sum_{j=1}^{2} w_j \sum_{k=1}^{2} w_{jk} v_{ijk} \quad (8)
\]

This can straightforwardly be generalized to multi-criteria decision trees of arbitrary depth and solved as corresponding multi-linear equations.

As was mentioned above, one of the problems with most models for criteria ranking is that numerically precise information is seldom available. We have solved this in part by introducing surrogate weights as before. This, however, is only a part of the solution since the elicitation can still be uncertain and the surrogate weights might not be a fully adequate representation of the preferences involved, which of course, is a risk with all kinds of aggregations. To allow for analyses of how robust the problem is to changes of the input data, we also introduced intervals around the surrogate weights as well as around the values of the technology options. Thus, in this elicitation problem, the possibly incomplete information is handled by allowing the use of intervals (cf., e.g., Danielson & Ekenberg, 1998, 2007), where ranges of possible values are represented by intervals (in combination with pure orderings without the use of surrogate weights at all, if the latter turns out to be inadequate).

There are thus several approaches to elicitation in MCDM problems, and one partitioning of the methods into categories is how they handle imprecision in weights and values, such as fixed numbers, comparative statements, representing orderings or intervals.

Computationally, methods using fixed numbers are very easy to solve, while systems of relational or interval constraints normally require more elaborated optimization techniques. On the other hand, if the model only accepts fixed numbers, we impose constraints that might severely affect the decision quality. If we allow for imprecision in terms of intervals and relations, we usually get a more realistic representation of the problem. These can, for instance, be represented by interval statements, such as \( w_i \in [y_i - a_i, y_i + b_i] \), where \( 0 < a_i \leq 1 \) and \( 0 < b_i \leq 1 \), or comparative statements, such as \( w_i \geq w_j \).

Systems of such equations can be solved, and aggregations of decision components in these formats can be optimized, by using the methods from (Ekenberg et al., 2011). The disadvantage here is that many decision-makers sometimes perceive these methods difficult to understand and accept, because of complex computations and loss of user transparency.\(^6\)

In this case, the performance of the different electricity-generation technologies was estimated from a larger expert survey. Together with the surrogate weights,\(^6\)

---

\(^6\) This should be kept in mind here as always when working with aggregation methods of whatever kind and this should affect how the elicitation mechanisms and software tools that are used.
they thus provided the decision base for the multi-criteria analysis. Using the weighted aggregation principle in (Eq. 8), we combined the multiple criteria and stakeholder preferences with the valuation of the different technology options under the criteria surrogate weights.

The results of the process were (i) a detailed analysis of each technology’s performance compared with the other technologies, and (ii) a sensitivity analysis to test the robustness of the result.

During the process, we considered the entire range of values as the alternatives presented across all criteria as well how plausible it was that an alternative outranked the remaining ones, and thus provided a robustness measure. Because of the complexity in these calculations, we used the state-of-the-art MCA software DecideIT for the analysis, which allows for imprecision of the kinds that exist here (Ekenberg et al., 2011). Earlier versions of DecideIT have been successfully used in a variety of decision situation, such as, storage of nuclear waste, insurance portfolios, demining and financial risks (Danielson et al., 2003; Danielson, 2005; Danielson & Ekenberg, 2007; Danielson et al., 2007).
RESUL\ts
The empirical data collected during the workshops allowed us to develop the following sets of results:
\- Stakeholders’ visions about the economic, societal and environmental future of Jordan.
\- Perceptions of risks and benefits of different electricity-generation technologies.
\- Rankings of different criteria.
\- Trade-offs of technologies, including results based on a modelling of criteria ranking.
\- Individual evaluations during the following up survey.
\- Discussion about energy transition in Arabic in the mass media and social media.

Visions of the economic, social and environmental future of Jordan

The majority of stakeholders groups perceive positive dynamic for the future of Jordan and lots of expectations are connected with economic growth, such Jordan being an economic leader in the region, or further development of manufacturing. Further expectations are expressed for development of different kinds of businesses due to improved environment for doing business or better cooperation among partners. Major expectations on drivers of economic development were connected with the reduction of debts and energy imports.

The perceptions about social future were more polarized. Indeed, there were expectations about further potentials development or job creation processes. At the same time concerns were expressed that the industrialised society will destroy traditional values or traditional family structure.

As about environmental future, hopes were expressed that at one side new technologies will allow reduction of human footprint and impact on environment. At the same time concerns were expressed about further limitations of existing in Jordan resources such as water scarcity.

The visions of positive and negative factors influencing the economic, social and environmental future of Jordan are described in tables 2 and 3. The detailed description of factors in each stakeholders group is provided in the annex.

Perceptions of risks and benefits of different technologies

The most frequently perceived benefits of PV were potentials for low costs electricity generation and for climate change mitigation. The most frequently named concerns were connected with high initial investment costs as well as technical risks such as intermittency, volatility and the need for storage (table 4).

Table 4: Perceptions of risks and benefits of utility PV
The most frequent benefits of CSP are low impacts on environment, potentials for climate change mitigation and high level of efficiency. At the same time, the perceived negative characteristics are high investment costs and land requirement (table 5).

Nuclear is perceived as a technology with low levelised costs of electricity, which generates sufficient quantities to cover the entire Jordanian growing energy demand. At the same time there are significant concerns about high risks for human health and environment in case of accidents. The nuclear waste and usage of water were two other discussed issues.

The detailed description of the discussions during the workshops is in the annex.

Ranking of different criteria

The ranking of different criteria during the six workshops with homogenous groups of stakeholders showed that electricity system costs are perceived as an important criterion by all groups of stakeholders. Safety and global warming potential are also perceived as important criteria. Safety has the highest important for decision-makers and is important for local communities, future decision makers and finance and investment. Global warming potential is important for local communities and for finance and investment. Global warming potential was a contested criterion, as it was perceived as the least important by academia. At the same time the domestic value chain integration was perceived as the least important criterion by almost all stakeholders groups, excluding academia and decision-makers. Non-emissions hazardous waste was the least important criteria for civil society, academia, future decision-makers and current decision-makers. Pressure on local land resources was ranked as the least important criterion for academia and pressure on local water resources was ranked as the least important criterion for decision-makers (table 12).

</table>

The ranking of the criteria by civil society and NGOs showed that electricity system cost is by far the most important criteria and weights more than one third in the decision making process when all ten remaining criteria make together less than 70%. During the round of open discussion after the ranking exercise the following arguments were discussed and the following criteria were debated as most important ones: electricity system costs, socio-economic impacts and safety.

There were following arguments for high importance of electricity system costs: “Currently the costs of renewable energies are high and there is an uncertainty in the costs prediction. At the same time the costs of fossil fuels are fluctuating less, they are fixed and the technology proved to be reliable. As the costs of renewable energy sources will go down, this will become more and more attractive option to satisfy energy demand. At the same time as energy demand growth will be significant fossil fuel power plants will still have to be maintained to guarantee baseload capacity and to cover the picks in case of additional demand.”

Socio-economic impacts were also mentioned as important in the following discussion: “It is important to use local resources and to facilitate technology transfer to create employment opportunities. Further regulatory and institutional frameworks are needed to facilitate technology transfer from Europe and the United States as well as from other countries to Jordan”.

Safety was discussed in light of further efforts which are needed to develop safety regulations for existing and emerging technologies. The question was also how to include safety regulations into national legislative framework.
For finance and investment stakeholders the main focus of discussion was on safety of electricity generation. Safety seems to be one of the most important criterion however the implementation of safety measures will lead to higher costs of energy. A further concern of participants was that safety-monitoring authorities in Jordan are lacking power to reinforce safety regulations. The responsibility level of stakeholders should be increased in order to guarantee safety of power plants operations. Participants believed that such technologies as nuclear power technologies will be transferred from more experienced countries, therefore the know-how and guarantees for safety will be also transferred.

During the open discussion among academia a severe debate took place between participants, who thought that electricity system cost is the most important criterion, and participants, who had a common understanding that safety is the most important criterion. In their opinion safety and security were vital. One participant summarized this sentiment in a sentence: “I need to be able to pay my electricity bills and have a wish to stay in good health without impacts of environmental pollution and safety risks of energy generation”.

Among future decision-makers electricity system costs criterion was considered as the most important one, especially in conditions of limited budget and budget deficit in Jordan. However, there was no consensus on this criterion among participants. Other participants were objecting strongly that values are more important then costs. Safety and transfer of knowledge were considered crucial for implementation of safety regulations. The risk of climate change impacts was also closely connected with safety issues.

Representatives of local communities intensively debated about what is more important, safety or impacts on human health and on locally available resources such as water and land. Also electricity costs are playing significant role for local communities. There was no common opinion on these criteria among different communities and the participants did not come to a compromise solution on which criterion is the most important one.

The discussion after ranking among decision-makers was short and participants agreed on the ranking and on the importance of the safety criterion. The aspect of safety was picked up again during the ranking of the procedural criteria where it was agreed that safety should remain top priority.

Procedural and output justice

Representatives of civil society and NGOs argued that every infrastructure project should be combined with implementation of participation procedures, namely, in framework of environmental impact assessment. These procedures should guarantee that local community would benefit from the project. Further sensibilisation of population is needed to guarantee sufficient level of awareness
and knowledge about the projects as well as about possibilities to participate. Two factors were intensively debated such as access to information, if it could be considered as participation or not, and compensation, namely, who should be responsible, how it should be organized and who should be compensated.

The main focus of discussion among **finance and investment** was about the access to information and meaningful participation. While some participants argued that access to information should be more a prerequisite for a meaningful participation, others argued that participation produces access to information. However, a consensus was reached that benefit sharing should come after the access to information and meaningful participation and that compensation should be the least important criterion. This is mainly because perceptions of participants that compensation is only due after the disaster occurred.

**Academia** intensively debated if providing information is a part of stakeholders’ involvement and inhabitants’ engagement or not. It was agreed that conditions for engagement should be provided during all phases of decision-making processes rather than compensating for adverse impacts of not inclusive and not transparent decision-making process.

Some participants among **future decision-makers** argued that participation in decision-making process should be prioritized. Participants initially had different ideas on what “access to information” means. It was argued that access to information reduces fear and enables participation; therefore, access to information should be the most important criterion. It was agreed that the access to information criterion should precede the participation criterion in the decision making process. Further it was decided that benefits should be ranked third, especially if the technology creates benefits for entire society, the state and the economy nationwide.

The aspects of involvement and participation were intensively discussed by **local communities.** It was agreed that community involvement into decision-making processes is the most important criterion, which should go much beyond simply informing and providing information. Even though availability of clear and transparent information is a necessary requirement. It was also agreed that compensation is the last criterion and that generally projects should be deployed to create communities as a better place to leave afterwards rather than simply compensating them for impacts from the projects.

**Decision-makers** agreed that awareness raising measures is a first step. Therefore, clear and transparent information should be available to stakeholders and inhabitants to guarantee public and social support for infrastructure deployment.
Trade-offs of technologies

Analysis and application of Decide IT software allowed identifying what do the preferences of stakeholders in terms of criteria mean for the most preferable technology (figure 2). The figure 2 shows an example of technology assessment. The detailed representation of results for each stakeholders group based on DecideIT is in the Annex.

The results for civil society and NGOs group show that utility PV is the most favorable technology, slightly better than coal and nuclear, followed by gas, large-scale hydro, oil shale, CSP, onshore wind and oil. There is a strong confidence that oil is considered much worse then most of the technologies and that coal, nuclear and gas are considered better then onshore wind, CSP, oil shale and large scale hydro. Significant role in these results is played by electricity systems costs criterion, which was considered one of the most important criterion and pushed to the top of the ranking coal, gas, nuclear and PV.

Utility PV was considered as the most favorable technology by finance and investment stakeholders group. Utility PV was slightly better than nuclear and large-scale hydro, followed by onshore wind, CSP, gas, coal, oil shale and oil. There is strong confidence that oil is worse then all technologies except oil shale and that utility PV, nuclear and large-scale hydro is better then all other technologies. Global warming potential is improving positions of most of technologies except coal, oil and gas. Electricity systems costs are pushing up coal, nuclear, gas and large-scale hydro.

For academia the utility PV was definitely considered as the most favorable technology followed by nuclear, oil shale, coal, gas, CSP, onshore wind, large-scale hydro and oil. There is strong confidence that oil is worse then all technologies except large-scale hydro, onshore wind and CSP. Utility PV was considered as a much better technology then all technologies except oil shale. Nuclear is much better then onshore wind, large-scale hydro and oil. Local air pollution is playing a role for these results and pulls back coal. Electricity systems costs are pushing up nuclear, coal and gas. On-site job creation is
considered being important for oil shale. At the same time pressure on water resources pulls this technology down.

The results in the group of future decision-makers show that utility PV is considered as the most favorable technology, slightly better than coal and nuclear, followed by gas, large hydro, CSP, onshore wind, oil shale and oil. There is strong confidence that oil is worse than almost all technologies except oil shale as well as that utility PV, coal and nuclear are better than all other technologies. Safety is an important criterion for stakeholders of this group. Also electricity systems costs are pushing up nuclear, coal and gas as well as PV.

In the group of local community representatives the utility PV is considered the most favorable technology, slightly better than coal and gas, followed by nuclear, onshore wind, large-scale hydro, CSP, oil and oil shale. There is a strong are confidence that oil shale is worse than all technologies and that utility PV and coal are better than onshore wind, large scale hydro, CSP, oil and oil shale. A safety criterion is playing a significant role for all technologies and is pulling down oil and oil shale. Electricity systems costs are pushing up nuclear, coal and gas. Pressure on local water resources is reducing positions of oil shale and nuclear. The availability of domestic resources is reducing positions of large-scale hydro.

Utility PV is considered as the most favorable technology by decision-makers. It is followed by oil shale, nuclear, coal, gas, large-scale hydro, onshore wind and CSP and oil. There is a strong confidence that oil is worse than most of technologies, except CSP, onshore wind and large-scale hydro and that utility PV is better than gas, large-scale hydro, onshore wind, CSP and oil. Electricity systems costs is considered as important criterion, which pushes up nuclear, gas and coal. Local air pollution reduces positions of gas and the availability of domestic resources criterion reduces positions of large-scale hydro. Pressure on water resources is reducing positions of oil shale and nuclear.

**Final workshop**

During the first round of the final workshop, where representatives from different groups of stakeholders were invited, utility PV was considered as the most favorable option followed by nuclear, gas and coal as well as CSP, large-hydro, onshore wind, oil shale and oil. There is strong confidence that oil is worse then utility PV, nuclear, gas and coal and that nuclear is better then CSP, large-hydro, onshore wind, oil shale and oil. Electricity systems costs are playing important role and pushing up nuclear, coal and gas. Local air pollution reduces positions of coal. On-site job creation is important for oil shale. Pressure on water resources reduces positions of oil shale and nuclear (figure 3).
Figure 3: Results for the first round of the final workshop

The final ranking during this workshop showed that utility PV is definitely the most preferable option followed by CSP, nuclear, oil shale, onshore wind, large-scale hydro, gas, oil and coal. There is strong evidence that coal is the least preferable option except oil and that utility PV is better than all other options and that CSP, nuclear and oil shale are better than oil and coal. Local air pollution is playing an important role for all technologies and is pushing down coal. On-site job creation is important for oil shale. Pressure on water resources is reducing positions of oil shale and nuclear. Electricity systems costs are less important than in previous round but still play a role together with local air pollution, on-site job creation and pressure on water resources (figure 4).
Figure 4: Results for the second round of the final workshop

The figure 5 shows the distribution of different technologies across the nationally and locally relevant criteria. The figure 5 shows the results considering the equal weighting of criteria. The figure 7 shows then the results with the compromise weighting of criteria.

Conclusions: “Ar. 1: Utility-scale Photovoltaic (PV)” is the best alternative, with “Ar. 2: Concentrated Solar Power” as runner up. The Ar. 1 = Ar. 2 statement is confident, since the information provided in this decision basis supports a short ranking with a degree of 22%, whereas the reverse statement is not supported.
Figure 5: Technology performance in the context of Jordan's national energy planning objectives and local impact sensitivity with equal weights.

On the horizontal axis is the index of the five criteria that are predominantly related to the objectives of the National Energy Strategy, whereas on the vertical axis the index of the six predominantly local criteria is plotted. Boundaries of the four quadrants are defined by the mathematical mean calculated for all eight technologies along the two criteria indices (Schinke and Klawitter, 2016).

The results show that technologies, which are at the top right quadrant, have the highest benefits and the lowest impacts across the national and local dimensions. For example, utility PV is at the top of the right quadrant, at the same time as oil is at its very bottom.
The figure 6 shows that solar PV also has the highest potential for societal support, at the same time as oil is the technology with the lowest potential for support.

The utility PV still remains the most favorable technology with the highest benefits and the lowerst impacts.
Figure 7: Technology performance along national and local criteria (compromise weights)

Also PV remains the technology with the highest potential for societal support (figure 8).
Our results show that during the final workshop with mixed groups of stakeholders some criteria were stronger disputed than other ones. The figure 9 shows the number of moves for each criterion during the first, second, third and forth rounds of the negotiation process.

The figure 9 illustrates the total moves which were made by participants for each criterion. It also shows which criteria were mostly discussed such as safety (24 moves), electricity systems cost (22 moves), pressure on local water security (17 moves and global warming potential (15 moves). At the same time pressure on local land resources (5 moves) and the use of domestic energy sources (5 moves) were almost not moved.
For instance, even though safety and electricity systems costs were considered as the most important criterion during previous six workshops with homogenous groups of stakeholders, during the final workshops stakeholders actively moved up and down these criteria.

The charts below show that some criteria were much more intensively debated than others. For instance, solutions were found quite quickly on such criteria as domestic value chain integration (figure 10).

The criterion on the pressure on local land use was also not intensively discusses (figure 11).
The major discussion happened between three criteria such as electricity system costs (figure 12), pressure on local water security (figure 13) or global warming potential (figure 14).

The analysis of moves for separate criteria showed that there was a divergency in opinion among different stakeholders. For instance, decision-makers and industry and finance had a common position on electricity systems cost criterion by moving this criterion always up in the ranking, like if they would like to say “electricity has to be delivered at the lowest possible costs and this is a top priority”. At the same time NGOs together with young people / future decision-makers were moving this criterion down for the sake of environmental criteria such as pressure on water resources.
Figure 15: Group convergence on electricity system cost criterion

The figure 16 on pressure on water resources shows an opposite to electricity system cost criterion, namely, that national NGOs together with academia and local communities were moving the criterion on pressure on water resources up and the industrial and finance stakeholders were moving it down.

Figure 16: Group convergence on pressure on local water resources criterion

It is also interesting to see that such criteria which were not contested in homogenous stakeholders groups as safety also show dynamic of moves among different stakeholders (figure 17).

Figure 17: Group convergence on safety criterion
The group convergence on safety criterion shows that representatives of NGOs and academia had similar positions by moving this criterion down. At the same time criterion was extremely important for decision-makers and also for young people / future decision-makers. Representatives from finance and industry as well as local communities had a rather neutral position towards this criterion where local community did not do any move.

The figure 18 and table 13 shows criterion with the highest ranking, namely, electricity system costs and safety were selected by several groups of stakeholders as criterion with the highest priority. At the same time opinion about these criteria is not homogenous. For instance, there was a higher divergence of opinions about the criterion of safety then about the criterion of electricity system costs. The biggest difference in opinions about safety criterion was among policy-makers, for whom safety has a high priority, and academia and national NGOs, who ranked this criterion as less significant.

The global warming potential was another criterion with high polarization of opinions, with local community representatives who ranked the criterion high, and academia and policy-makers, who ranked the criterion low. Pressure on local water security and non-emission hazardous waste were two criteria which received a low ranking but where positions of stakeholders were homogenous. National NGOs and academia ranked technology and knowledge transfer and on site job creation significantly higher then local community and policy-makers. The use of domestic energy sources was also a criterion with high polarization of opinions which was ranked high by decision-makers, national NGOs and academia, and received a low ranking from finance and industry as well as local communities.

**Individual preferences**

The following results are describing individual preferences, which were received during the stakeholders’ survey, distributed to participants six months after the last stakeholders workshop. These results allowed us to validate results received during the focus group discussions (for detailed description of results please see the annex).

The majority of respondents were satisfied with the ranking of criteria (53%) and very satisfied (27%). However, the share of respondents who were not satisfied was also significant (22%), which shows that our stakeholders group was not homogenous and that there was a conflict in opinion about electricity generation technologies. Also the majority was satisfied (64%) and very satisfied (17%) with the final ranking of technologies. Some respondents were also unsatisfied with the ranking (18%).
The respondents also had an opportunity to rank criteria and technology individually. The survey results showed that utility PV and CSP were ranked as the most attractive technologies and electricity costs and safety were ranked as the most important criteria.

These results show that individual ranking followed the same pattern as the ranking during the final workshop. The major difference was regarding criteria and technology in the middle of the ranking (table 14).

These results show that the most important and the least important criteria remained the same. For instance, electricity costs and safety are the most important criteria during both rankings. Global warming potential is the least important criteria.

Second, during the survey ranking several socio-economic criteria were moved up, such as domestic energy use, job creation, domestic value chain generation. The criterion on technology and knowledge transfer was moved down but this is mainly due to the fact, as the discussions during the workshops showed, that technology and knowledge transfer was perceived already as a part of domestic value chain generation was perceived.

Third, environmental criteria were moved to the bottom of the ranking, with waste having the same place in both rankings, but pressure on air quality and health as well as the pressure on water security were moved to the bottom. Pressure on land was moved up, but mainly due to the fact that technology and knowledge transfer was moved down as a least important criterion together with global warming potential.
Finally, the most preferable technologies remained the same, such as PV and CSP being on the top of the ranking. However, nuclear and coal were moved to the bottom of the ranking, with coal being the least favorable technology and nuclear losing from the place number 3 to the place number 7. Oil and oil shale improved both their positions, with shale oil being more popular than oil. Onshore wind and gas also improved their positions. Also the large-scale hydro remained the same.

**Analysis of discussion about energy transition in Arabic language in mass media and social media**

During the entire year 2017 we used the Gavagai Monitor, which is a media-monitoring tool and is based on the general theory of distributional semantics (Magnus, 2008). The tool is implemented through the self-learning Random Indexing framework (Kanerva et al., 2000). The background semantic model of term-term association is built through observing the occurrences and cooccurrences of terms in natural text, which are used to infer relationships between terms (Sahlgren et al., 2016). The system takes as input the definition of a target of interest through a number of terms entered by the user and it suggests supplementary terms strongly associated with the given ones using the background semantic model. When the suggested target is specified appropriately, the system tracks mentions of it in on-line media and displays them in a line graph to demonstrate volume of mentions over time.

Analysis of sentiment in text is a new and rapidly growing field of study and application. The various human ranges of subjectivity such as emotion, attitude, mood, affect, sentiment, opinion, and appeal all contribute to the basic categories of sentiment analysis of text, and have been studied in their own right for a long time in the behavioural sciences rather than in technology. For the purposes of media monitoring, the surface manifestation of human subjectivity in writing can be considered to be encoded mostly in lexical choice: in selecting terms, which are appropriate to the attitude in question. Which aspects of subjectivity are most useful for a task is an editorial decision to be made by the responsible analyst (Karlgren et al., 2012).

The goal was to understand discussions on energy sources in the Arabic language media. Karlgren screened all available editorial media, such as news sites and news streams, as well as the journals, social media such as blogs,

---

7 The data collection and analysis was performed by Prof. Jussi Karlgren (KTH – The Royal Institute of Technology, Stockholm)
forums, and discussion boards, real-time microblogs also including BBSes and Twitter.

The main focus of this research was on energy solutions in Jordan. This allowed the tracking of public opinion on a vast array of questions and issues and the assessment what is important to the general public. Karlgren targeted the following terms:

1. Oil
2. Coal, shale, gas
3. Hydroelectric power
4. Nuclear power
5. Solar power
6. Wind power

Besides the terms mentioned above, Karlgren also tracked a number of topical aspects to capture foreseeable aspects of public discourse. These attitudes were:

1. Trustworthy
2. Politics, controversy
3. Pollution
4. Waste
5. Safety
6. Expertise, competence and authority
7. National interest

The results (for more details please see the annex) show that the discussion about oil and nuclear power is much more intensive than on any other power source. This discussion is also influenced by the regional drivers, like the current deal between US and Iran, which has significant political implications for deployment of nuclear in the Middle East.

Solar energy is also mentioned frequently and is actually the third most discussed electricity source in the media. The news coverage about solar tends to be positive. There is also a certain degree of curiosity in the solar development (figure 18).
These results show that there is also a certain desire for technology. At the same time also concerns about solar technology are expressed.

5. Conclusions

The results of group and individual rankings of criteria and technologies as well as of discussions about the visions about future of Jordan and discussions about importance of different criteria allowed us development of following conclusions.

Conclusion 1: utility PV remains the most favorable technology. It was ranked as the top priority in frames of all stakeholders groups. Also during the final ranking with the mixed group of stakeholders utility PV was ranked at the top of the list. During the individual ranking stakeholders also ranked PV as the most favorable technology. Other solar technology, such as CSP, is ranked significantly lower. The main reason is high investment costs of this technology.

Conclusion 2: the discourse about energy transition in Jordan is strongly dominated by energy security concerns. In almost all group rankings safety of energy generation as well as affordability of electricity prices were ranked as a top priority. The criteria, which are relevant for social and environmental impacts of technologies, were moved at the middle or the bottom of the ranking. It seams that concerns about climate change mitigation do not belong to the dominant discourse as criterion on climate change mitigation was frequently
ranked at the bottom of the list. One stakeholder group, the local communities, ranked global warming potential at the top of the ranking, probably, because people on the ground are feeling direct impacts of climate change. However, while evaluating the renewable energy technologies the most frequent positive characteristic was “clean” and “with little impact on environment”. It seems that there is a certain level of awareness about environmental protection issues however the level of awareness about climate change risks and the need for climate change mitigation is lower.

Conclusion 3: comparison of visions of environmental, social and economic future of Jordan showed that the young people have the most optimistic approach. For instance, they did not identify no one negative tendency. Among economic factors, the positive expectations connected with investment into new technologies and reduction of dependency on energy imports were mentioned most frequently. The positive expectations about social development are connected with creation of employment opportunities and generation of further knowledge. In general, there was a perception that environmental future of Jordan is positive. Among negative tendencies the possible increase of electricity costs were named most frequently. In the social area this is the destruction of traditional values and of traditional family structure. In environmental areas the most frequent concerns were about water scarcity.

Conclusion 4: by discussing about procedural and output justice, the majority of stakeholders had the opinion that compensation for deployment of infrastructure should be the least favorable criterion and that further efforts are necessary to facilitate engagement of stakeholders and laypeople into decision-making processes on energy transition. Providing possibilities for participation in decision-making processes was considered as the most important criterion among four criteria of procedural and output justice.

Conclusion 5: solar, nuclear and oil are three mostly discussed in the Jordanian media in connection to the energy generation technologies. However, attitudes to these technologies are quiet different. Solar is perceived mostly positively, with PV being a top priority technology. At the same time CSP does not enjoy the same high level of support as PV. Nuclear was often considered as a second or third favorable technology. However, the opinions here are strongly polarized and several stakeholders are strongly against nuclear. Even though oil is being discussed frequently in media, it is considered as a least favorable technology by all groups of stakeholders. Shale oil is considered much more positive, mainly due to available in Jordan resources and aspirations for technology transfer and impulses for socio-economic development, which are connected with the deployment of this technology.

Conclusion 6: the strong recommendation from stakeholders during almost all workshops was to add oil shale technology as one of the most discussed in Jordan. In some stakeholders groups, such as academia or local communities, there was also recommendation to add waste to energy technology with the
major arguments about its positive features such as possibilities to reduce costs of waste disposal, clean technology and potentials to create green jobs.

Question 2: If Jordan wants to decrease its energy import dependency, how do you evaluate the future potential of each electricity-generation technology to contribute to this goal?

Please take into account your judgment of proven non-renewable and renewable energy sources and the likelihood of the resources to be exploits and used for electricity-generation until 2040.

Table 22: Data on local air pollution and health

Figure 27: Data on local air pollution and health
Annex 2: Electricity-generation technologies in Jordan

Photovoltaic: A photovoltaic system, also known as the PV system or solar power system, is a power system designed to supply usable solar power by means of photovoltaic technology. Photovoltaic cells directly convert solar radiation into electricity by exploiting the photovoltaic effect using semiconductor materials (Kaltschmitt et al., 2007).

A PV system consists of an arrangement of several components, including solar collectors to absorb and directly convert sunlight into electricity, a solar inverter to change the electric current from DC to AC, as well as mounting, cabling and other electrical accessories (Kaltschmitt et al., 2007).

In 2016, 12 PV projects including direct offers and the commercial operation to generate electricity with a capacity of 200 MW became operational. Currently, the capacity of these projects is at 428 MW (Marar, 2017):

- With 10 MW, the Philadelphia Solar Power Company IPP PV project direct proposals round I was achieved in October 2015 in Mafraq. This is the “first-of-its-kind” project connected to the distribution network.
- In 2016, different PV projects with the overall capacity of 200 MW became operational. The projects were realized by international and local companies.
- In October 2017, the 13 MW Zatari Solar PV project became operational. The project was financially supported by a German grant.
- In April 2015, the 5 MW Azraq Solar PV project became operational. The project was supported by a Spanish grant and implemented on the basis of the EPC contract.
- In 2017, more than 200 MW of small-scale net-metering rooftop systems and solar PV projects became operational.

Jordan considers PV to be an important technology, and several PV projects are currently in the planning or implementation phases (Marar, 2017). These projects include the following:

- PV projects with a total capacity of 200 MW (50 MW each) in the developmental zones of Al-Mafraq region and Safawi/Azraq. The MEMR signed four memoranda of understanding to achieve financial closures for these projects. It is expected that they will become operational in 2018. The agreed tariff for electricity reached an unprecedented low (ranging between 43-55 fils/kWh).
- PV project with a total capacity of 103 MW in Qweirah/Aqaba. The project is currently developed by the consortium TSK and Enviromena, is under the engineering, procurement and construction EPC contract and is funded by
In October 2016, Masdar, a clean energy developer based in Abu Dhabi, UAE, signed a Power Purchasing Agreement to build a solar power plant with the overall capacity of 200 MW in Muwaqqar. The project is due for completion in 2018.

Small Scale Solar PV System projects with a capacity of 80 MW are currently under construction.

**Concentrated Solar Power:** The CSP technology concentrates solar radiation using mirrors onto a receiver, and then converts it into thermal energy inside the receiver and transfers it to a heat transfer medium. According to published reports and an announcement by the Ministry of Energy and Mineral Resources (MEMR), the CSP projects are still not implemented in Jordan. The MEMR points to higher technology investment costs compared to those of PV.

**On-shore wind:** Wind energy converters (WEC) harness the kinetic energy contained in flowing air masses. Jordan has favourable conditions for wind power generation regarding wind speed and long periods of windy weather. Currently, there are wind projects with a capacity of 197 MW in operation, and projects with a capacity of 171 MW are under construction (Marar, 2017).

In 2017, the following wind projects were in operation:

- Tafila Wind Farm, which is the first large-scale renewable energy IPP in Jordan with the overall capacity of 117 MW.
- The Ma’an wind project, with the first phase of 66 MW capacity, which became operational in September 2016 and the second phase of 14 MW capacity, which became operational in September 2017.

In 2017, the following wind projects were under construction:

- Direct proposals round I with a total capacity of 330 MW in southern Jordan. Purchasing power agreements were signed with five different companies. All projects are expected to become operational in the year 2018.
- The Korean KEPCO direct offer in al-Fjej/Shoubak with a capacity of 90 MW is expected to be operational by the end of 2018.

**Utility hydro-power:** Hydropower plants harness the potential energy within falling water and use classical mechanics to convert that energy into electricity. A hydroelectric power station, depending on scale, normally consists of a dam or weir, and the system components intake works, penstock, in some cases a headrace, plus the powerhouse and tailrace (Kaltschmitt et al., 2007).

Conventional hydropower resources in Jordan are limited because surface water resources are almost negligible. The available generation capacity of hydropower projects is 12MW (NEPCO, 2016). In 2017, there were two small hydroelectric plants, the King Talal Dam with a rated capacity of five MW and a
scheme at Aqaba thermal power station which utilizes the available heat of returning cooling seawater with a capacity of six MW (CEGCO, 2017). Currently, no plans for an expansion of conventional hydropower capacity exist.

**Nuclear power:** Nuclear power plants split uranium atoms inside a reactor in a process called fission. At a nuclear energy facility, the heat from fission is used to produce steam, which spins a turbine to generate electricity. The central region of Jordan has reserves of 40,000 metric tonnes of uranium, which can supply Jordan for 150 years (Jordan Times, 2017).

In 2017, several decisions were taken to continue with the plans for the use of nuclear power. The Nuclear Power Plant Commission in Jordan will implement the first Jordanian nuclear power plant site in Amra. The Jordan Atomic Energy Commission (JAEC) announced that Rosatom's reactor export subsidiary Atomstroyexport (ASE) will be the supplier of two nuclear units on a build, own and operate (BOO) basis including third generation and technology of Russian reactors with a capacity of 1,000 MW each. Jordan's first nuclear reactor is expected to start operating in 2024 succeeded by the second reactor two years later (MEMR, 2016).

**Coal:** Coal-fired power plants convert the chemical energy that is embedded in coal into heat, i.e., the fuel is burned, and the heat released during the combustion is captured. The heat is then used to generate steam, which drives a steam turbine generator to produce electricity.

The first power plant in Jordan that runs on coal will be operational by 2025 with a capacity of 30 MW. It will be located in Qatraneh, in the south of Jordan. The agreement was signed in 2016 between MEMR and the Al Manaseer Group. The project is part of Jordan's energy strategy, under which five per cent of power will be generated by coal by 2025 (Jordan Times, 2016).

**Natural gas:** The natural gas power stations utilize the kinetic energy of motion of flowing gas or the potential energy of a gas under pressure to generate electricity via a gas turbine. Most gas-fired power plants use natural gas as a fuel, while other gases and fuels could also be used including distillate fuel oil, hydrogen and gases produced by gasification, such as the gases in IGCC power plants.

In 2016, the electricity generated by natural gas in Jordan was 75.6 per cent of all electricity generated (NEPCO, 2016). MEMR seeks to achieve the strategic objective of increasing the contribution of natural gas in the total energy mix (MEMR, 2016).

There are currently many large-scale power plants in Jordan that work with natural gas. Some of them are:

- Aqaba Thermal Power Plant (capacity of 656 MW)
- Risha power plant (capacity of 120 MW)
Rehab power plant (capacity of 357 MW)
Samra power plant (capacity of 1.168 MW)
Amman East power plant (Al Manakher) (capacity of 375 MW)
Qatrana power plant (capacity of 375 MW)
Independent Power Plant 1 Amman East Power Plant (capacity of 380 MW)
Independent power Plant 2 Al Qatrana Power Plant (capacity of 373 MW)
Independent Power plant 3 (capacity of 570 MW)
Independent Power Plant 4 (capacity 240 MW)
Hussein Repowering power plant (capacity of 485 MW).

Oil: The oil-fired power plant uses the chemical energy of oil to generate electricity with the help of different kinds of steam systems. In general, the year 2016 witnessed the decrease in the consumption of oil products by around 21 per cent. This was due to the falling demand for oil products used in electricity-generation and the replacement of this fuel by large quantities of imported natural gas. The decrease in consumption amounted to 64 per cent for fuel oil and 23 per cent for diesel.

Annex 3: Visions about economic, social and environmental future

Group 1 (civil society and NGOs)

Economic: The main vision of stakeholders in Group 1 is that Jordan—compared to other countries of the region—is an economic leader in the region. Participants expect large engineering efforts, which will take place in the coming years and that these efforts will help Jordan to attract investment. This investment, including both public and private financing, will become an economic driver in the country. They also envision Jordan to be a country of stability and peaceful development. They believe that the international community will support multiple efforts to keep that stability because of its vivid interest in Jordan. They also believe that there is an interest to keep Jordan as a stable stronghold in the region. Due to its stable internal and political situation, they consider Jordan to be the best place in the Middle East for exploring renewable energy sources. Stability and resilience to conflicts in Jordan is also closely interlinked with its economy. International and regional policies are playing an important role in keeping the country stable despite the fact that national politics are rather unpredictable. Energy is needed to sustain economic growth. Several options will be implemented such as waste-to-energy generation and biogas power stations. Also a more sustainable usage of energy will be introduced with a transformation of the transportation system to a more sustainable and eco-friendly fuel usage. However, the existing technologies and resources will not suffice to cover the growing energy demand, and some
participants expressed the view that nuclear power will be needed to balance energy supply and demand and to provide base load. Such a stable situation and economic growth should be closely connected with efforts to preserve the environment and to reduce the impact from economic growth and energy-generation on eco and bio systems. The economic situation, however, is likely to be challenged by several new features of Jordanian domestic economic policy. These include an increase in taxes, increased pressure from refugees on the economic system and a worsening banking situation. Also, youth unemployment will result in a further deceleration of the Jordanian economy and a possible decrease of the living standards.
Social: Potential conflict with refugees, increased criminal activities, a growing population and stress on the labour market pose significant risks to the social situation. But there is the chance that by 2040, refugees will have returned home. There is also the expectation that several employment opportunities will be created in the service sector. A significant increase in the population because of migration and growing urbanization constitute a risk to food security. Measures that will be taken to address food security issues will result in increased land degradation and water shortage. Therefore, policies are needed today to address these risks for the future. Such policies ought to include improved urban planning policies and strategies to prevent the formation of informal settlements. Strategies are also necessary to keep the traditional family structure.

Environment: The group has positive expectations about the environmental development as during recent years there have been significant attempts to reduce pressure on the environment. These changes are connected with the changing behaviour of people and of their habits. There are also expectations that the use of renewable energy sources will contribute to a further decrease in the pressure on the environment. Current and future water scarcity is one of the most acute environmental challenges. Water reserves will be affected by a growing population, unsustainable waste management issues, the destruction of forest resources, unsustainable land use issues connected with energy generation. Water scarcity and unsustainable agricultural patterns will be interconnected with decreasing agricultural production within Jordan and increasing reliance on the import of agricultural products. Soil degradation is another important problem, which arises from the effects of climate change, increased droughts, deforestation and soil degradation. There is a need for more efforts to protect the soil from impacts of climate change. There is also a need for increased efforts in reforestation and the control of desertification. In general, stakeholders of this group see a good potential for a “green life” trend within society. This trend will lead to a cleaner environment and an improved usage of water. They are also optimistic as concerns expectations regarding changes in the transportation system towards a more eco-friendly fuel as well as technologies that will be implemented to merge waste management with energy production and the establishment of biogas plants.
Group 2 (finance and investment)

Economy: This group of stakeholders expects that renewable energy will reduce dependency on energy imports and thus contribute to reducing government debts, which are connected with expensive energy imports. Renewable energy will also contribute to political stability in the region and will create independence from energy imports. Solar power in particular will make a positive contribution as it could be implemented at different scales and components can potentially be manufactured locally and . However, further efforts are needed to reduce the costs and necessary volumes of investment in renewable energies. In general, the group believes in a positive economic development in the coming years, which will give the people of Jordan more choices and options . However, there are also negative tendencies. These tendencies are a growing budget deficit as well as increasing tax burdens. Energy transition might also result in benefits for some and disadvantages for others. A growing population and increased energy consumption is likely to result in a less reliable energy supply. There is doubt whether the energy supply needed can be produced by renewable energy sources only. Using renewable energy sources will lead to increased levelized costs of electricity due to the need to finance high investment costs of this technology. Unstable energy demand will lead to an increase in energy prices as well as a devaluation of the local currency. While oil shale is expected to contribute significantly to reducing Jordan's dependency on energy imports it is expected that its production volume will grow slowly as current capacities and investment flows in this area are low.

Social: The level of awareness of renewable energy sources, both centralized and decentralized, will increase. This awareness will include the knowledge about electric mobility technologies and energy efficiency. It is expected that renewable energies will contribute to decentralized solutions and the establishment of self-sufficient smart cities. The use of renewable energy sources will improve public education and create opportunities for people in this field. The group was convinced that family structures will change in the future, from a traditional family to more single person households. This will be due to the availability of new technologies that facilitate living on one’s own.

Environment: In general, cities in Jordan will become cleaner and greener and also less reliant on fossil fuel resources. Green building standards will be implemented. The level of environmental pollution will be reduced. PV and geothermal technology will play an important role in reducing environmental pressure from energy generation. The major shift towards a more environmentally friendly environment will happen as the level of awareness increases about the need to mitigate pressure on the environment. Many opportunities in the area of green growth will also arise.
Group 3 (academia)

**Economy:** This group envisages a better and tighter cooperation between the private and the public sector, which will benefit the entire Jordanian economy. Government debt is expected to decrease but it is the group’s belief that all necessary measures to decrease it should be introduced now. In the mid-term future, Jordan will become an electricity exporter after having installed nuclear power plants, increased the share of renewable energy sources and use of oil shale. This will create further job opportunities and lessen the stress on the government’s budget. However, to foster such positive development it is necessary to improve transparency and accountability in the energy sector. An extensive population growth in combination with no governance reforms would magnify the risk of an economic crisis in Jordan.

**Social:** Through a diversified energy production landscape and a wider use of local resources, the group believes that the poverty level will go down, and the quality of life will improve. The group was mainly concerned about the changing family values, morals and ethics in the Jordanian society. They also fear that the currently existing social divide among different population groups will widen. They are cautiously optimistic about the contribution of green growth to socio-economic development. However, it is necessary to make the population even more aware of the impacts of climate change and, therefore, to step up such awareness-raising measures so that the Jordanian society will indeed change its life style. While green growth will also have a positive impact on society as it will reduce the poverty rate, the necessary skills needed for green growth have to be fostered now. Young people, who represent a large share of the population, will become leaders of change. They will help to rebuild the middle class and to redistribute wealth more fairly. A more vigorous exchange of knowledge between Jordan and international experts will also drive socio-economic change.

**Environment:** The group believes that international and regional cooperation will be the driver for reducing the pressure on the environment. However, there is no common opinion about Jordan’s environmental future. A part of participants expect a cleaner and greener environment while others think that besides water scarcity, air, land and water pollution will increase. There is also no common opinion about the feasibility of 100 per cent green society, however the common belief is that a transfer of renewable energy technologies is necessary and that it will benefit the Jordanian society.
Group 4 (future decision-makers)

**Economy:** The participants of this group expressed hope for decreasing debts and a falling level of poverty as well as for more significant impulses for socio-economic development, such as job creation processes. Major drivers of socio-economic development, according to these participants, will be connected with a higher reliance on locally available resources for energy-generation and -consumption, such as oil shale and renewable energy sources. They considered that oil shale could well contribute to energy security of Jordan.

**Social:** Group participants connected green growth mainly with new arising economic opportunities and the creation of new direct, indirect and induced jobs. Green growth will also lead to new educational opportunities and improve existing educational capacities. This higher level of education will create additional positive drivers for socio-economic development.

**Environment:** In general, the group participants’ expectations were that the future environment will be cleaner and greener, mainly as a result of reduced environmental impacts, especially by such sectors as energy and construction. They believed that the currently ongoing awareness-raising campaigns will result in a higher level of environmental awareness among the Jordanian population.

Group 5 (local communities)

**Economy:** This group’s participants believed that the economic development will be characterized by a stronger participation of the private and public sectors in the implementation of several investment projects and in increased levels of efficiency resulting from this cooperation. The use of locally available energy sources will lead to a reduction of the government debts as well as to the creation of opportunities for energy export. The use of renewable energy sources will be connected with and contribute to an improved environment for investment. This, in turn, will help to attract further investment.

**Social:** They posit that society will be more aware of the impacts of climate change and the need to reduce pressure on the environment. This increased level of awareness will result in a greater acceptance of energy transition and renewable energy sources as well as in a more open-minded society. They also cautioned that it is likely that some traditional values will get lost in the course of this transition.

**Environment:** The group is convinced that the level of CO2 emissions will be reduced significantly as a result of the use of non-fossil energy sources. Technologies such as waste-to-energy, renewable energies, nuclear power but also the implementation of energy efficiency measures will significantly contribute to this. This way of generating energy will contribute to reduced impacts on the environment, will be cleaner and more sustainable.
Group 6 (political decision-makers)

Economy: The group considers the energy sector to be especially important for the economic development in Jordan. A transfer of new technologies as well as the lower energy prices, which will result from the use of domestically available energy sources, will be a significant driver for socio-economic development and will help to attract further foreign direct investment. To attract private investment in energy generation and transmission projects, further privatization efforts are needed in the energy sector. Improvements in the energy sector will also be a driver for improvements in other related sectors such as agriculture and manufacturing. However, opinions about the future economic development of Jordan were polarized. Some participants expected more positive development while others expected a more negative economic situation. There was no common opinion in the group about future energy prices, as some participants expected they would go down and others thought that they would go up and would put additional pressure on households, resulting in social instability as people might find it difficult to cover their basic needs.

Social: The group believes that energy transition will lead to a transformation of family values and the creation of more single households as well as a decreasing number of traditional families. But it also had a positive perception of the role of Jordan in the region, as a country that has provided shelter for refugees, thus shown a sense of responsibility towards the challenges it has been confronted with. They also appreciated the community belonging and solidarity of the Jordanian society and saw its society as open-minded with a significant degree of social freedom. They considered water availability to be the major challenge and source of potential conflicts. This challenge has to be addressed in light of the growing population and migration to the country caused by the refugee crisis. The lack of communication among different stakeholders involved in water security policy issues is one of the major barriers to policy implementation and measures designed to solve this challenge. While the government always leads such efforts, the involvement of further stakeholders is necessary. The group members see a connection between the use of new technologies and the creation of new employment opportunities. But they are also aware that further awareness raising measures are needed to increase social and public acceptance as well as willingness to use these technologies. A more intense cooperation of the public and private sector in the use of these new technologies will lead to further positive impulses for socio-economic development.

Environment: In adapting to impacts of climate change Jordan has to learn from its past and will have to reduce pressure on the environment. There is also an urgent need to transform the existing transportation system in Jordan to reduce environmental pressure. In the area of energy generation, waste-to-energy technology has significant potentials. Once this technology is implemented, there will be a significant reduction in the environmental footprint. Further improvements could be achieved by using renewable energy sources and nuclear power.
**ANNEX 4: Discussion about benefits and risks of different technologies**

**Group 1 (civil society)**

They also value **photovoltaics (PV)** as positive as it is green energy, creates clean technology jobs and helps to reduce losses in grids by generating electricity on-site. It also contributes to achieving climate change mitigation targets and energy security targets such as the reduction of energy imports. Yet, PV also has some negative sides such as intermittency risks or the need for recycling after 30 years.

Several participants evaluate **concentrated solar power (CSP)** positively, describing it as a clean technology that has a possibility for storage, less impacts on the environment and a possibility for small and large-scale projects. It also contributes to stabilizing the grids and to providing the base load. They point out that the flaws of CSP are the need for battery replacement as well as intermittency due to variations in the solar irradiation.

The positive features of **wind energy** correspond to those of other renewable energies: clean technology, unlimited resources, no pollution as well as possibilities for small and large-scale implementation. The negative sides are noise, difficulties in maintenance and costs.

They rate **hydropower** as negative mainly because of the absence of water resources in Jordan.

They also consider **nuclear power** as negative because it produces waste, poses high risks for human health and the environment in case of accidents and needs water for cooling. It also needs additional units to guarantee stand-by, and the overall costs of this technology are high.

**Coal** has positive sides such as a good contribution to the energy mix and balancing of baseload. At the same time, it contributes substantially to the pollution of the environment by emissions or to climate change. There are also some environmental safety issues.

**Gas** has its pros and cons: On the one hand, concerning energy security, Jordan would depend on imports of this resource. It is also an expensive technology. On the other, participants consider it to be relatively clean in terms of greenhouse gas emissions and a technology that can provide back-up capacities.

The advantage of **oil** is that it guarantees stable delivery in terms of quantities. Its disadvantages are connected with environmental problems such as CO₂ emissions as well as prices and availability.
Group 2 (finance and investment)

Participants of this group consider PV as a clean and inexpensive technology, which is easy to maintain and which has no negative impact on the environment. They view it as the most environmentally friendly technology as it produces no greenhouse gas emissions and uses an abundant energy source. PV is currently connected with increasing efficiency and decreasing costs. The downsides of this technology are relatively high investment and electricity costs, variability and intermittency.

Participants judge CSP as clean and sustainable, with a possibility for storage, though at the price of expensive technology.

Wind is a clean energy, produced by an abundant (free) energy source, and requires little land space for power generation—thus is very efficient. Jordan’s potential for wind generation is considerable, with several places with high wind speeds. Many of the group consider it to be the “way to the future”. This technology is environmentally friendly and does not require significant maintenance efforts. It also does not produce greenhouse gas emissions. At the same time, it is not really reliable as turbines usually fail to produce electricity below 30 per cent capacity. It has high initial costs, is loud and noisy. Its initial costs are high and it affects the beauty of landscapes.

The group members perceive hydropower to be a clean, environmentally friendly energy source, connected with low costs and easy maintenance, high efficiency and a low impact on the environment. Its major drawbacks are the lack of water in Jordan and environmental impacts on land areas.

Participants consider nuclear power as the technology with one of the least levelized costs of electricity, that is very efficient and that produces excellent output. At the same time, it requires water, is connected with high risks to human health and the environment, including pollution by radiation, high running costs, and the initial capital costs are high.

The pros of gas are that it is clean, inexpensive, efficient, common and there are low initial costs. The major downside is modest natural gas reserves in Jordan, the fact that it is resource intensive and has detrimental effects on the environment.

Even though the group members perceive oil as a reliable technology, they also acknowledge that it is not sustainable, connected with high costs, harms the environment and has a high resource intensity. In using oil, the country will become dependent on the fluctuation of prices and processes in global economics, which can result in high oil prices.

The group considers coal to be less expensive, readily available and the option that has the lowest cost–electricity-generation ratio. At the same time, it causes high levels of air and land pollution and thus puts significant pressure on the environment.
Group 3 (academia)
Members of this group regard PV as a clean, environmentally friendly and low cost technology with improving efficiency of operations. This technology also leads to savings of greenhouse gas emissions and helps to reach national climate change mitigation targets. It is easy to use and can be made available almost anywhere there is sunlight. Its price is also acceptable. Its disadvantages are that it requires storage batteries, is not domestically developed yet and that there are no production sites in Jordan. It also cannot satisfy all demand.

CSP, too, is a clean energy, which is available in Jordan. It can be used for future electricity generation, can be stored and used for large projects. One major drawback is that due to the large size of power stations this technology may not always be suitable for local conditions. Power stations also require large amounts of water and land. High initial investment costs may also be a hindrance.

Wind has a small environmental footprint and is cost effective. There are also good locations for wind generation in Jordan. It can be combined well with PV. It is also a clean technology that does not cost much. Disadvantages are that electricity from wind is intermittent, is only moderately efficient and is high in initial costs. Wind turbines have negative impacts on the environment, are noisy, and the technology is not manufactured locally.

Hydropower is a clean, reliable and cheap technology. However, it is connected with high initial costs, and there is a significant shortage of water in Jordan.

Nuclear power is cost efficient and can cover all existing Jordanian demand. It can be produced on a large scale and deliver electricity to large consumers such as big cities or energy-intensive industries. It is also able to provide a stable baseload. Its downsides are that there are high risks such as radiation and the handling of nuclear waste. It also requires significant amounts of water for cooling and operating the power station. In case of political instability, a nuclear facility is at the risk of being misused.

Gas is available in the region, and the large-scale deployment of gas capacities does not require a modification of the grids. Also, pollution from gas is limited. The issue with gas is that there are several supply issues as gas must be imported.

Oil is available in the region. It is also available in countries whose socio-cultural conditions are similar to Jordan. At the same time, it pollutes the air, and it is expensive. It is also affected by fluctuation of the prices on international markets. Also political risks can influence supply of oil.

Coal is a cheap technology, which can provide a good baseload. But it has impacts on the environment and is not available in the region but has to be imported.
Group 4 (future decision-makers)

**PV** is clean and there is a lot of space in Jordan, which could be suitable for its deployment. It can be deployed on rooftops of existing buildings. The source is available everywhere. It can be constructed in any size. It is not connected with greenhouse gas emissions and can be effectively used by private households. It also can provide jobs and there are good potentials in Jordan for local manufacturing of components. At the same time it uses some toxic chemicals like cadmium. It can produce electricity only when sun shines and requires storage options. It needs more research to increase its efficiency. It is intermittent and initial costs are still high. It requires large areas and is also prone to dust accumulation.

**CSP** can produce electricity for large-scale projects. It is also carbon free and the level of efficiency of power stations is high. At the same time it is expensive, it requires large volumes of water and it does not have potential in Jordan.

**Wind** has low level of pollution. There are good potentials for wind in Jordan. This is also a highly efficient technology and land below windmills could be used for other purposes. At the same time it is connected with high costs, it is still not dispatchable, it is noisy and has impacts on birds.

**Hydro** is effective and very clean technology. It is also highly efficient and projects can be deployed for long time. The problem is low water availability in Jordan, also the need to identify places with different heights. It is connected with high initial costs.

**Nuclear** was perceived as very highly efficient technology for electricity-generation, which also creates many jobs. At the same time the radiation can be very harmful for human health and lead to cancer. There is also low level of acceptance for nuclear among people. It is a risky technology. It is costly and needs lots of water for cooling and operation. The nuclear waste is a big problem.

**Coal** is very cheap. It is dispatchable. But the negative sides are that it is not clean, it requires investment and is not available locally. Coal is suitable for small-scale industries, it is very reliable and provides job opportunities. It is also cheap and if combined with carbon capture and storage can be also clean. At the same time it is polluting, it has high impacts on environment and it is not available in Jordan.

**Gas** is the lowest cost technology with stable baseload. However, it has high import costs, it is not available in Jordan and it also produces emissions and impacts on environment.

**Oil** has high level of pollution, it is not available in Jordan. It is connected with high costs, produces emissions and has high impacts on environment.

---

Group 5 (local communities)
PV is the cheap technology, which can be integrated at any level. It is clean and can be developed in remote areas. It is easy to finance and electricity generated by PV is cheap. It is suitable to install and is easy to maintain. At the same time it is an intermittent technology. The picks of its electricity-generation are not synchronized with the picks of its electricity demand. If it is deployed at scale it requires a lot of surface. It is not stable and needs cleaning.

CSP can provide stable base load and high temperatures for industry. At the same time it is expensive, requires high initial investment and is difficult to install.

Wind is the cleanest technology from all renewables. It is available everywhere and does not require lot of land for deployment. Its electricity relatively cheap and it can be deployed in remote areas. At the same time it requires high initial costs of investment, has no storage and is a noisy technology. Its electricity-generation is also not stable.

Hydro is clean and is widely used in several countries. It can provide stable and dispatchable electricity-generation. At the same time it needs certain topography and is not feasible in Jordan because of the shortage of water.

Nuclear was described as feasible technology, which guarantees energy security. With technology transfer of nuclear to Jordan know-how and skills are coming. At the same time there are issues with safety, it requires high capital investment. It is usually of large size and requires huge volumes of water. Skills in Jordan for nuclear are not developed.

Gas is cheap, clean and dispatchable. It is easy to finance and the local skills exist. It can guarantee stability of the grids and has high efficiency. At the same time the negative side is the lack of gas reserves within Jordan.

Coal was perceived mainly as a polluting technology, which is dangerous for human health and environment.

Oil was also perceived as polluting technology which is dangerous for human health and environment.

**Group 6 (political decision-makers)**

CSP is a safe technology, which has low impacts on environment. It is also clean and can contribute to climate change mitigation. It has high efficiency and high concentration ration. At the same time it has high initial costs and requires extensive maintenance. It also needs a lot of space.

PV is clean and feasible for Jordan. It has short payback period. It is clean and is the cheapest technology. But it does not generate too many jobs, it is prone to grids disturbances, its efficiency is low, it requires a lot of space.
Wind is safe to use and provides cheap electricity. It has low costs and is efficient. It is also clean and does not require land resources. It is easy in operation and maintenance. It can use local resources. At the same time it is noisy, it has higher operation and maintenance costs than other renewable energy sources. It is very site specific and cannot be deployed everywhere.

Hydro is efficient and controllable. It has high number of employees. Its maintenance and electricity-generation is cheap. However, there is a lack of water in Jordan and therefore it is not feasible.

Coal is cheap but at the same time it is not clean, it is not safe due to the lack of advanced technology, it is connected with high initial costs. It has negative impacts on human health and environment. This is an old technology, which will become more expensive as once coal resources are limited.

Gas can provide a baseload in electricity mix provided by renewable energy sources. However, it is not ideal for Jordan due to the absence of domestically available resources.

Oil creates dependencies as the resource is not available in Jordan and therefore it will increase the state debt. It has impacts on human health and creates air pollution. It also produces waste and waste water.

Nuclear can cover growing energy demand with cheap and reliable electricity. At the same time it is connected with high risks for human health and environment and it also produces waste and requires a lot of water.

Final workshop discussion

This section summarizes arguments, which were brought by representatives of different stakeholders groups on importance of different criteria.

Finance and private sector: use of domestic energy sources is less important as there are no domestic energy sources in Jordan. Also on site job creation is important as the number of jobs in renewable energy sector is low and could be higher.

Academia: Electricity system costs are important. The last few years have been challenging for Jordan. Expensive energy imports have led to national debt, which affects other areas of society and economy. Therefore, the costs are the most important criteria. Use of domestic energy sources is linked to electricity system cost. Renewable energies and oil shale are the solution. Transfer of knowledge is important but domestic expertise exists. Water resources criteria is important as Jordan has severe water shortages and water must be considered to support technologies. Renewable energies can be a solution for air pollution. Job creation criteria is important as jobs should be created locally to support local communities. Safety is important as nuclear energy is a huge safety issue. Renewable energies are not considered to be unsafe. Global warming potential is
not an important criteria as Jordan is not a heavy industry state. It is not significant in comparison to other countries.

**Young leaders:** Safety is the most important criteria as human life is the most precious thing we have. Electricity system costs are also the most important criteria as Jordan is a poor country and cannot effort expensive electricity. Local air pollution is also an important criteria as is related to safety.

**Local communities:** Impacts of technologies on the community is the most important aspect. New technologies need to be specifically focused on issues of safety and maintenance. Electricity System Costs is an important criteria as it affects many sectors in life. Knowledge needs to be transferred to communities to make communities more susceptible to new technologies. New technologies should reduce pressure on water resources. Job creation is important but other criteria should be focused on more. If they are achieved then job-creation will follow naturally. Global warming is not an important criteria as its impacts are too uncertain.

**Decision-makers:** Government has three pillars for decision-making processes: cost, sustainability and job creation. Safety should be the first priority. Electricity system cost are important in Jordan, energy costs is a big problem which puts pressure on the government budget. Renewable energy and shale oil could contribute to energy independence. A new grid is needed to integrate renewable energies. Land needs to be considered carefully and is a main criteria for the government.

### ANNEX 5: Ranking of criteria

**Group 1 (civil society and NGOs)**

The electricity system cost criteria is followed by such economic criteria as use of domestic energy sources, technology transfer and on-site job creation. Interestingly that criteria of impact on local communities such as pressure on water, air and land as well as waste remained at the bottom of the ranking.

Table 23: ranking of criteria by civil society and NGOs

<td>4</td>
<td>12</td>
</tr>
</tbody>
</table>
Group 2 (finance and investment)

The ranking of the criteria by finance and investment (table 24) showed that global warming potential and safety are two most important criteria, followed by electricity system costs. As in the previous group, domestic value chain integration was ranked at the bottom of the ranking.

Table 24: ranking of criteria by finance and investment stakeholders

</tr>
</tbody>
</table>

Group 3 (academia)

The ranking of the criteria by academia (table 25) showed that electricity system costs is by far the most important criteria. This criteria is followed by use of
domestic energy sources, technology transfer, pressure on water and air, as well as criterion of jobs.

Table 25: ranking of criteria by academia

<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

Group 4 (future decision makers)

The ranking of future decision makers (table 26) showed that safety and electricity system costs are two most important criteria. This was followed by criteria of social and environmental impact of a technology, such as on-site job creation, technology and knowledge transfer as well as pressure on local resources. Waste was ranked at the bottom, as well as the domestic value chain integration, as in many other stakeholders groups.

Table 26: ranking of criteria by future decision-makers communities

<td>11</td>
</tr>
<tr>
<td>Technology and knowledge transfer</td>
<td>0</td>
<td>11</td>
</tr>
</tbody>
</table>
Group 5 (local communities)

The ranking of the criteria by local communities (table 27) showed that global warming potential was ranked as the most important criteria. This was the only group of stakeholders, which ranked the global warming potential as the most important one, probably, because people on the ground are feeling directly the impacts of climate change. Safety and electricity system costs were also considered as most important criteria. In this group also environmental criteria such as pressure on water, land and air resources as well as waste were considered much more important then by other stakeholders groups. Domestic value chain integration was the least important criteria.

Table 27: ranking of criteria by local communities

<td>2</td>
</tr>
</tbody>
</table>
Group 6 (political decision-makers)

The ranking of political decision-makers (table 28) showed that criteria, which are important for electricity planning process were considered as the most important ones. For instance, safety was considered as the most important criteria because this is the task of the government at the national and local levels to control the risk. But also the use of domestic energy sources and electricity system costs were considered as very important criteria, which are essential for energy security policy and also for socio-economic development, which is connected with the electricity prices.

ANNEX 6: Trade-offs of technologies

*Group 1 (civil society and NGOs)*

**Figure 28:** preferences of civil society and NGOs stakeholders group

**Conclusion:** “At 1. USB-scale Photovoltaics (PV)” is the best alternative, with “At 6. Coal” as runner up. The At 1 ≠ At 6 statement is not tenable, since the information provided in this decision basis supports a dichotomous ranking with a degree of 5 %, whereas the reverse statement is not supported.
Group 2 (finance and investment)

Conclusion: "At 1:1 Utility-scale Photovoltaics (PV)" is the best alternative, with "At 6:6 Naphtha" as runner up.

The At 1 > At 5 statement is not confident, since the information provided in the decision basis supports a weak ranking with a degree of 7 %, whereas the reverse statement is not supported.

Figure 29: preferences of finance and investment stakeholders group
Group 3 (academia)

![Graph showing preferences of academia stakeholders group]

**Conclusion:** "All 1 Utility scale Photovoltaic (PV)" is the best alternative, with "All 5 Nuclear" as runner up.

The All 1 - All 5 statement is consistent, since the information provided in this decision basis supports a strict ranking with a degree of 21%, whereas the reverse statement is not supported.

Figure 30: preferences of academia stakeholders group
**Group 4 (future decision makers)**

![Preferences Graph]

**Conclusions:**

- **Case 1 (Utility-scale Photovoltaics (PV))** is the best alternative, with
  - **Case 1** in the leading position.
- The **Case 6 (Coal)** statement is not confident, since the information provided in this decision matrix suggests a strict ranking with a degree of 4%, whereas the reverse statement is not supported.

**Figure 31:** Preferences of young leaders / future decision-makers

**Group 5 (local communities)**

![Diagram of preferences of local communities stakeholders group]

Conclusions: "All 1 Utility-scale Photovoltaics (PV)" is the best alternative, with "All 6 Coal" as runner-up. The All 1 = All 6 statement is not confident, since the information provided in this decision basis supports a strict ranking with a degree of 3%, whereas the reverse statement is not supported.

Figure 32: preferences of local communities stakeholders group
Group 6 (political decision-makers)

Figure 33: preferences of political decision-makers stakeholders group

Conclusions: "All 1 Utility-scale Photovoltaic (PV)" is the best alternative, with "All 9 Oil shale" as runner up.
*The All 1 = All 9 statement is mildly confident, since the information provided in this decision basis supports a strict ranking with a degree of 13%, whereas the reverse statement is not supported.*
ANNEX 7: Individual preferences

Figure 34: Satisfaction with the final criteria ranking

The figure 34 shows the level of satisfaction with the final criteria ranking. The respondents were asked “How satisfied are you with the final ranking of criteria?” It shows that the majority of respondents were satisfied and very satisfied with the results. However, almost 20% were not satisfied with the results of final ranking.

Figure 35: Satisfaction with the final criteria ranking of technologies

The figure 35 shows how satisfied the participants were with the final ranking of technologies. The respondents were asked the question “How satisfied are you
with the final ranking of technologies? It shows that the majority of stakeholders were satisfied and very satisfied with the final ranking of technologies. However, the share of stakeholders who were not satisfied is also around 20%.

The figure 36 shows individual ranking of technologies when respondents were asked during the survey to rank technologies by themselves. The question was “How will you rank technologies individually?” It shows that renewable energy sources such as utility PV, CSP and onshore wind were ranked as the most favorable technologies. At the same time nuclear, oil and coal were ranked as the least favorable technologies.
The figure 37 shows individual ranking of criteria. The respondents were asked the question "How will you rank criteria individually?". The majority of stakeholders ranked criteria, which are relevant for national energy security such as electricity costs, safety and the use of domestic energy sources, as the most important criteria.

To the question "Would you agree to provide your government with ranking developed during the final workshop as a recommendation for Jordan’s energy policy?" More then 94% of all respondents answered "yes" and 5% were undecided.
