In a recent paper, V.F. Demyanov, S. Gamidov and I. Sivelina developed an algorithm for solving optimization problems, given by smooth compositions of max-type functions.

In this paper the authors apply this algorithm to a larger class of quasidifferentiable functions.

This paper is a contribution to research on nondifferentiable optimization currently underway with the System and Decision Sciences Program.

On the steepest descent method for a class of quasi-differentiable optimization problems

D.Pallaschke, P.Recht

O. Introduction

In a recent paper V.F.Demyanov, S.Gamidov and T.J.Sivelina presented an algorithm for solving a certain type of quasidifferentiable optimization problems [3].

More precisely, they considered the class $\mathcal{F}$ of all functions given by

$$\mathcal{F} = \{ f: \mathbb{R}^n \rightarrow \mathbb{R} \mid f(x) = F(x, y_1(x), \ldots, y_m(x)) \} ,$$

where

$$y_i: \mathbb{R}^n \rightarrow \mathbb{R} \quad \text{is defined by}$$

$$y_i(x) = \max_{j \in I_i} \phi_{ij}(x) \quad I_i = 1, \ldots, N_i; \quad i = 1, \ldots, m$$

and

$$\phi_{ij}: \mathbb{R}^n \rightarrow \mathbb{R} \quad \text{for all } i \in \{1, \ldots, m\} \text{ and all } j \in I_i .$$

The functions $F$ and $\phi_{ij}$ under considerations are assumed to belong to the classes $C_1(\mathbb{R}^{n+m})$ and $C_1(\mathbb{R}^n)$ respectively.

The optimization problem consists in minimizing a function $f \in \mathcal{F}$ under constraints.

In this paper we will apply the minimization algorithm of [3] to another class of quasidifferentiable functions.

We are able to prove for this type of optimization problems a convergence theorem similar to that in [3].

- 1 -
1. Steepest descent method

We will shortly recall the steepest descent algorithm for minimizing a quasidifferentiable function in the unconstrained case.

Let \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) be a quasidifferentiable function.

Then for every \( \tilde{x} \in \mathbb{R}^n \) there exist two compact, convex sets \( \tilde{f}_\tilde{x} \) and \( \tilde{f}_\tilde{x} \), such, that for every \( g \in \mathbb{R}^n, \|g\|_2 = 1 \), the directional derivative is given by:

\[
\frac{df}{dg}|_{\tilde{x}} = \max_{v \in \tilde{f}_\tilde{x}} \langle v, g \rangle + \min_{w \in \tilde{f}_\tilde{x}} \langle w, g \rangle.
\]

Here \( \langle , \rangle \) denotes the canonical inner product in \( \mathbb{R}^n \).

In terms of these two sets, a steepest descent direction for \( f \) at \( \tilde{x} \) is given by

\[
g|_{\tilde{x}} := g(\tilde{x}) = -\frac{v_o+w_o}{\|v_o+w_o\|_2}.
\]

with

\[
\|v_o+w_o\| = \max_{w \in \tilde{f}_\tilde{x}} \left( \min_{v \in \tilde{f}_\tilde{x}} \|v+w\|_2 \right).
\]

Now, in the steepest descent algorithm, we start with an arbitrary point \( x_0 \in \mathbb{R}^n \).

Let us assume that for \( k \geq 0 \) the point \( x_k \in \mathbb{R}^n \) has already been defined, then define

\[
x_{k+1} := x_k + \alpha_k \cdot g(x_k),
\]

where \( g(x_k) \) is a steepest descent direction of \( f \) at \( x_k \) and the real number \( \alpha_k \geq 0 \) is choosen in such a way, that

\[
\min_{\alpha \geq 0} f(x_k + \alpha g(x_k)) = f(x_k + \alpha_k g(x_k)).
\]

Obviously, the sequence \( (x_k) \) induces a monotonously decreasing sequence \( (f(x_k)) \) of values of the function \( f \).

A modification of the steepest descent algorithm is proposed in [3]. Therefore we define:
Definition: Let $\varepsilon, \mu$ be positive real numbers and $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be quasidifferentiable. Let $N$ be a neighbourhood of all points $x \in \mathbb{R}^n$, where $f$ is not differentiable. Then for $x_0 \in N$ we define:

$$
\overline{\partial}_\varepsilon f|_{x_0} := \text{conv} \left( \bigcup_{s \in \mathbb{R}^n} \overline{\partial} f|_{x_0 + s} : \|s\|_2 \leq \varepsilon \right)
$$

$$
\overline{\partial}_\mu f|_{x_0} := \text{conv} \left( \bigcup_{s \in \mathbb{R}^n} \overline{\partial} f|_{x_0 + s} : \|s\|_2 \leq \mu \right)
$$

If $x_0 \notin N$, then $\overline{\partial}_\varepsilon f|_{x_0} := \overline{\partial} f|_{x_0}$ and $\overline{\partial}_\mu f|_{x_0} := \overline{\partial} f|_{x_0}$.

If $\overline{\partial}_\varepsilon f|_{x_0}$ and $\overline{\partial}_\mu f|_{x_0}$ are compact sets, then $f$ is called $(\varepsilon, \mu)$-quasidifferentiable in $x_0$.

With the introduction of these two sets, we now give a modified steepest descent algorithm to find an $\varepsilon$-inf-stationary point $x^*$ of $f$.

Let us assume that $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is quasidifferentiable and moreover that, for given $\varepsilon, \mu > 0$, it is $(\varepsilon, \mu)$-quasidifferentiable. Then choose an arbitrary $x_0 \in \mathbb{R}^n$. Suppose, that $x_k$ has already been defined.

If $-\overline{\partial} f|_{x_k} \subset \overline{\partial}_\varepsilon f(x_k)$ then $x_k$ is an $\varepsilon$-inf stationary point and the algorithm stops.

Otherwise, if $-\overline{\partial} f|_{x_k} \not\subset \overline{\partial}_\varepsilon f(x_k)$, then compute

$$
g(x_k) := -\frac{v_o + \omega_o}{\|v_o + \omega_o\|_2}
$$

with

$$
\|v_o + \omega_o\|_2 = \max_{w \in \overline{\partial}_\mu f|_{x_k}} \left( \min_{v \in \overline{\partial}_\varepsilon f|_{x_k}} \|v + w\|_2 \right)
$$

and define $x_{k+1} := x_k + \alpha_k g(x_k)$, where $\alpha_k > 0$ is chosen in such a way, that

$$
\min_{\alpha \geq 0} f(x_k + \alpha g(x_k)) = f(x_k + \alpha_k g(x_k)).
$$
In this paper we want to apply this modification for finding an ε-inf stationary point for a class of quasidifferentiable functions.

2. A motivating example

Let \( F, G: \mathbb{R}^n \rightarrow \mathbb{R} \) be two arbitrary functions with \( F, G \in C_1(\mathbb{R}) \). Then define the following, quasidifferentiable function \( f: \mathbb{R}^n \rightarrow \mathbb{R} \) by

\[
 f(\mathbf{x}) = \max(|G|, -F|G|) - ||G|| - 2|F|.
\]

This type of function is considered in [1] and does obviously not belong to the class \( \mathcal{F} \), defined in the introduction. For illustration in figure 1 the graph of a function \( f \) of such a type is given for

\[
 F: \mathbb{R}^2 \rightarrow \mathbb{R}, \quad F(x_1, x_2) = x_1^2 - x_2
\]

\[
 G: \mathbb{R}^2 \rightarrow \mathbb{R}, \quad G(x_1, x_2) = -x_1^2 - x_2^2 + 1.2
\]

in the set \( \Omega=[-1,1.4] \times [-2,1.25] \).

For functions of that type, as well as for the class \( \mathcal{F} \), the following properties are valid, as observed in [3].

I. If for all \( x \in \mathbb{R}^n \), the convex, compact sets \( \partial \frac{3f}{3x} \) and \( \partial \frac{3f}{3x} \) are computed as in [3] the two mappings

\[
 x \mapsto \partial \frac{3f}{3x} \quad \text{and} \quad x \mapsto \partial \frac{3f}{3x}
\]

are upper-semi-continuous. Moreover for suitable \( \varepsilon, \mu > 0 \) the function \( \frac{3f}{\varepsilon} \), \( \frac{3f}{\mu} \) are also upper-semi-continuous.

Figure 1
II. If $x \in \mathbb{R}^n$ is not a stationary point, then there exist a real number $M > 0$ and a neighbourhood $U_0$ of $0 \in \mathbb{R}^n$, such that for all $y \in U_0$

$$\left| \frac{df}{dg} \right|_{x} - \frac{df}{d(g+y)} \right|_{x} \leq M \cdot \|y\|^2.$$ 

3. A convergence Theorem

**Theorem:**

Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be a quasidifferentiable function with the following properties:

(i) There exist real numbers $\varepsilon > 0, \mu > 0$ such that for all $x \in \mathbb{R}^n$ $f$ is $(\varepsilon, \mu)$-quasidifferentiable and the mappings

$$x \mapsto \frac{\partial f}{\partial x} \big|_{x}, \quad x \mapsto \frac{\partial^2 f}{\partial x^2} \big|_{x}$$

and

$$x \mapsto \frac{\partial f}{\partial x} \big|_{x}, \quad x \mapsto \frac{\partial^2 f}{\partial x^2} \big|_{x}$$

are upper semi-continuous (u.s.c.)

(ii) If $x \in \mathbb{R}^n$ is not an $\varepsilon$-inf stationary point, then there exist an $M > 0$ and a neighbourhood $U_0$ of $0 \in \mathbb{R}^n$ such that for all $y \in U$, $g \in \mathbb{R}^n$

$$\left| \frac{df}{dg} \big|_x - \frac{df}{d(g+y)} \big|_x \right| \leq M \cdot \|y\|^2.$$ 

Then: Every limit point of the sequence $(x_n)_{n \in \mathbb{N}}$, constructed by the modified steepest descent algorithm, is an $\varepsilon$-inf stationary point of $f$.

**Proof:**

Let $x^*$ be a limit point of $(x_n)_{n \in \mathbb{N}}$ and let us assume, that $x^*$ is not $\varepsilon$-inf stationary. Hence there exist a $v_0 \in \partial_\varepsilon f \big|_{x^*}$ and a $w_0 \in \partial f \big|_{x^*}$ such that

$$\|v_0 + w_0\|_2 = \sup_{w \in \partial f \big|_{x^*}} \left( \inf_{v \in \partial_\varepsilon f \big|_{x^*}} \|v + w\|_2 \right) = a > 0.$$
Thus $g := -\frac{v^o + v^o}{\|v^o + v^o\|^2}$ is a normalized descent direction in $x^*$.

Observe that $w^o \in \delta_x f$.

Since $x \mapsto \frac{f(x)}{x}$ is u.s.c., there exist a neighbourhood $\tilde{U}$ of $\frac{f(x)}{x}$ and a neighbourhood $U$ of $x^*$ such that for all $x \in U$

$$\frac{f(x)}{x} \in \tilde{U}.$$

Moreover, to $\frac{f(x)}{x}$ there exist a neighbourhood $\tilde{V}$ of $\frac{f(x)}{x}$ and a neighbourhood $V$ of $x^*$ such that for all $x \in V$

$$\frac{f(x)}{x} \in \tilde{V}.$$

Choose $U_0$ according to assumption (ii) of the theorem. To $W := U \cap V \cap (U_0 + x^*)$ there exists a $k_0 \in \mathbb{N}$ such that for all $k \geq k_0$, $x_k \in W$. (Here $k$ is the index of the convergent subsequence.)

Let us denote by $w^*_k \in \frac{f(x)}{x}$ the point, which is nearest to $w^o$.

From the upper semicontinuity of $\frac{f}{x}$ we have

$$\lim_{k \to \infty} w^*_k = w^o.$$

Now, let $v_k \in \frac{f}{x}$ be a point of minimal distance to $-w^*_k$.

Then $\lim_{k} (\text{dist}(v_k, \frac{f}{x})) = 0$.

This follows from the fact, that for every $k$ (large enough)

$$\text{dist}(v_k, \frac{f}{x}) \leq \delta \text{Hausd.} \left( \frac{f}{x}, \frac{f}{x^*} \right),$$

which tends to 0 by the choice of $\tilde{U}$.

The neighbourhoods of $\frac{f}{x}$ can be assumed to be bounded, since $\frac{f}{x}$ is compact.

Hence, there exists a subsequence $(v_k)$, also indexed by $k$, which converges to $\tilde{v} \in \frac{f}{x}$.

Thus, for a suitable subsequence and an index $K$ we have:

$$\lim_{k \to \infty} \|w_k + v_k\|^2 = \|w^o + \tilde{v}\|^2 \geq \text{dist}(w^o, \frac{f}{x}) = a.$$
We see that $\tilde{v}=v_0$ since the Euclidean norm is strict. Therefore, for all $k > K$
\[
\left\| w_k + v_k \right\|_2 \geq \frac{a}{2}
\]

Now, we want to show, that for $k$ large enough
\[
\bar{v}_k = -\frac{v_k + w_k}{\left\| v_k + w_k \right\|_2}
\]
is a descent direction in $x^*$.

For this, let $\alpha > 0$. Then:
\[
f(x_k + \alpha \bar{v}_k) = f(x^*) + \frac{df}{d\left[ (x_k - x^*) + \alpha \bar{v}_k \right]} \bigg|_{x^*} + O(\left\| x_k - x^* \right\|_2)
\]

From assumption (ii) follows
\[
\frac{df}{d\left[ (x_k - x^*) + \alpha \bar{v}_k \right]} \bigg|_{x^*} = \alpha \frac{df}{d\bar{v}_k} \bigg|_{x^*} + O(\left\| x_k - x^* \right\|_2)
\]
and therefore
\[
f(x_k + \alpha \bar{v}_k) = f(x^*) + \alpha \frac{df}{d\bar{v}_k} \bigg|_{x^*} + O(\left\| x_k - x^* \right\|_2)
\]

By definition of quasidifferentiability we have:
\[
\frac{df}{d\bar{v}_k} \bigg|_{x^*} = \min_{\bar{v} \in \Delta f} \left( \max_{w \in \Delta f} \langle w + v, \bar{v} \rangle \right)
\]
and therefore, by definition of $v_k$:
\[
\frac{df}{d\bar{v}_k} \bigg|_{x^*} \leq \max_{v \in \Delta f} \left( -\langle w_k + v, w_k + v_k \rangle \| w_k + v_k \|^{-1} \right)
\]
\[
\begin{align*}
&= -\|w_k + v_k\|_2^2 \cdot \|w_k + v_k\|_2^{-1} = -\|v_k + w_k\|_2 \leq -\frac{a}{2}.
\end{align*}
\]

Since
\[
\frac{df}{dg_k}\bigg|_{x^*} \leq \max_{v \in \mathbb{U}} \langle v, \hat{g}_k \rangle + \min_{w \in \delta f} \langle w, \hat{g}_k \rangle,
\]

we find for a given \(\delta > 0\) an index \(K_1\) such that for all \(k \geq K_1\)

\[
\frac{df}{dg_k}\bigg|_{x^*} \leq \max_{v \in \mathbb{U}} \langle v, \hat{g}_k \rangle + \min_{w \in \delta f} \langle w, \hat{g}_k \rangle
\]

\[
\leq (\max_{v \in \mathbb{U}} \langle v, \hat{g}_k \rangle + \delta) + \langle w_o, \hat{g}_k \rangle
\]

\[
\leq (\max_{v \in \mathbb{U}} \langle v, \hat{g}_k \rangle + \delta) + \langle w_k, \hat{g}_k \rangle + \|w_k - w_o\|_2
\]

\[
= \frac{df}{dg_k}\bigg|_{x_k} + 2\delta \leq -\frac{a}{2} + 2\delta.
\]

Thus, for all \(k \geq K_1\), we see that \(\hat{g}_k\) is a descent direction in \(x^*\).

Hence, there is \(\tau_o > 0\) such that

\[
f(x_k + \tau_o \hat{g}_k) < f(x^*).
\]

Now, by the definition of the sequence \((x_k)\) via the modified steepest descent algorithm we have:

\[
f(x_{k+1}) = f(x_k + \alpha_k g(x_k)) = \min_{\alpha > 0} f(x_k + \alpha g(x_k))
\]

\[
\leq \min_{\alpha > 0} f(x_k + \alpha \hat{g}_k) = f(x_k + \alpha \hat{g}_k)
\]

\[
\leq f(x_k + \tau_o \hat{g}_k) < f(x^*).
\]
This contradicts the facts that \((f(x_k))\) is monotonously decreasing and \(\lim f(x_k) = f(x^*)\).  

\[ \forall k \in \mathbb{N} \]

\[ \text{QED.} \]

Remark: The proof also remains valid for \(\varepsilon = 0\), i.e. replacing "\(\varepsilon\)-inf-stationary" by "inf-stationary".

4. Numerical experiences

The above mentioned modification of the steepest descent method was implemented on the Siemens 7780 at the Computer Center of the University of Karlsruhe.

Applying this procedure to the motivating example of section 2, \(\varepsilon\)-inf stationary points, also for problems under constraints, (cf. (2)) could easily be found.

Let us now discuss a further example

Let \(f: \mathbb{R}^3 \rightarrow \mathbb{R}\) be given by

\[ f_1(x_1, x_2, x_3) = \left( (x_1 + x_2) + \sqrt{(x_1 - x_2)^2 + 4x_3^2} \right) / 2 \]

and

\[ f_2(x_1, x_2, x_3) = \left( (x_1 + x_2) - \sqrt{(x_1 - x_2)^2 + 4x_3^2} \right) / 2 \]

with:

\[ f(x_1, x_2, x_3) = |f_1(x_1, x_2, x_3)| - |f_2(x_1, x_2, x_3)| \]

Obviously \(f_1, f_2 \in C_1(\mathbb{R}^3)\).

This function naturally occurs in the investigation of condition of matrices, namely if we assign to any symmetric \((n \times n)\)-matrix \(A = (a_{ij})_{1 \leq i, j \leq n}\) the difference of moduli of the maximal and minimal eigenvalue \(|\lambda_{\text{max}}|\) and \(|\lambda_{\text{min}}|\) respectively, i.e.

\[ \varphi: L(\mathbb{R}^n, \mathbb{R}^n) \rightarrow \mathbb{R} \]

\[ \varphi_n(A) = |\lambda_{\text{max}}| - |\lambda_{\text{min}}| \] .

This function is quasidifferentiable, since \(\sup_{\|x\|=1} <Ax, x>\) is a convex function and \(\inf_{\|x\|=1} <Ax, x>\) is a concave function.
For $n = 2$, $\phi_n$ coincides with the above defined function $f: \mathbb{R}^3 \rightarrow \mathbb{R}$. Moreover, the properties i) and ii) of the theorem are valid for the sets $\mathbb{B}_\varepsilon f$ and $\mathbb{B}_\mu f$ for suitable $\varepsilon$ and $\mu$. Figure 2 below gives an illustration of the graph of the function $f$ for 4 different values of $x_3$, i.e. $x_3 = 0.3; x_3 = 0.2; x_3 = 0.1; x_3 = 0.0$. 

Figure 2
eventual consequence of the pictures of Figure 2.

Interestingly, the "commutative character" of Clarke's subdiffer- 
ence could find a descent direction $(0,0,0)$. Moreover, any 
subdifferential of a regular function at a point $0$ is an inner point of the Clarke 
minimum or maximum, nor a saddle-point, but it is neither 
In Clarke's sense, the point $(0,0,0)$ is stationary, but it neither 

In Example 2.1 of [4],

The behaviour of the function $x^3 = 0$ is similar to that, given.
