## 1. Detailed Methods

**Global field size dataset:** The field size data were collected through a crowdsourcing campaign using Geo-Wiki (<http://www.geo-wiki.org>), which is an application that involves the crowd in visual interpretation of very high resolution satellite imagery. During one campaign that was focused on human impact (See et al., 2015), volunteers were asked to interpret field sizes located in cropland areas in a 1 km<sup>2</sup> sample area using the following 4 categories: 1 (very small); 2 (small); 3 (medium) and 4 (large). The data gathered from this campaign consisted of 53,000 samples of 1 km<sup>2</sup> areas, of which around 36,000 were at unique locations. Of these unique locations, 13,963 samples contained cropland and therefore the size of the field. This sample data set of ordinal values was then interpolated using inverse weighted distance, treating the ordinal values as a continuum, to create a global map of field size at a 1 km<sup>2</sup> resolution, which was then clipped using the IIASA/IFPRI cropland map (Fritz et al., 2015). The global field size map can be downloaded from <http://www.geo-wiki.org>.

The field sizes have been roughly correlated to areas as follows: a field size of very small corresponds to fields that are smaller than 0.5 ha; small fields correspond to an area of 0.5 to 2 ha; medium fields to between 2 and 100 ha; and large fields are all fields larger than 100 ha. These field sizes were derived by measuring the size of fields found inside the 1 km<sup>2</sup> areas and by adjusting, in particular, the large field size based on comparisons of large fields in representative areas and using expert judgment from members of the GEOGLAM initiative (<http://www.earthobservations.org/geoglam.php>).

The field size map was validated in two ways. The first type of validation was to assess the reliability of the crowd. A random sample of the field size data collected during the campaign was provided to multiple experts and then correlated with the data obtained from the crowd. This resulted in a Spearman's rank correlation coefficient of 0.80, indicating an acceptable agreement. The second form of validation was to consider the effect of interpolation by randomly choosing a new set of samples from the interpolated map, comparing these to the field sizes determined by multiple experts from visual interpretation of very high resolution imagery. In total, 181 validation points with field sizes ranging from very small (1) to large (4) were used. The results indicate a Spearman's rank correlation coefficient of 0.78. Given that the global map was developed using only 13,963 points, this agreement is considered to be satisfactory. More details of the validation process can be found in Fritz et al. (2015).

**Farm size distributions:** Currently there are no farm-size distribution data for the globe. Lowder et al. (2014, 2016) compiled much information on the topic, drawing from census data. Two issues associated with these data are that the country coverage is incomplete, and that the information is based on many different years of census data (and some of the data are from the 1960s). The approach taken here was to calculate regional average farm size distributions for the regions of interest, update the number of farms to more recent values, where possible, and then use these regional distributions on a country-by-country basis to derive farm sizes on a national basis, on the assumption that the structure of agriculture in different countries of a region exhibits some essential similarities. In this way, a farm-size distribution can be estimated for any country, provided that data exist for the total number of farms in the country. The more recent the information on number of farms in the country, the better, given that farm size distribution in many countries may be changing over time for a variety of reasons. Out of the 163 countries in our analysis, data on number of farms for 138 countries were available in Lowder et al. (2014), and estimates for the remaining 25 were found from online sources, either from census data or, as a last resort, estimated from rural population and household size data. For the 167 countries that Lowder et al. (2014) found data for, the total number of farms was 569.6 million; this included several small island states excluded from our analysis. For our study's 163 countries, we calculated a total of 577.2 million farms. The countries in this analysis and their regional allocation are shown in Table S2.

To allocate national production statistics to the different farm sizes at a country level, we used the spatially explicit global dataset on field-size distribution described earlier (Fritz et al., 2015). This dataset is based on a 1-km resolution cropland percentage map for the baseline year 2005 overlaid with field size data collected via a crowdsourcing campaign. For each country, we calculated the relative proportion of four different field sizes, "very small" (<0.5 ha), "small" (0.5-2 ha), "medium" (2-100 ha) and "large" (> 100 ha). We then imputed a plausible field size distribution to the country's farm size distribution (using either national or regional data), using three simple rules, so that the national (non-spatial) farm size areas matched the national (spatial) field size areas:

- The distributions should be monotonically increasing, monotonically decreasing, or unimodal; i.e., smooth distributions rather than simply random selections.
- Any allocation reflects the assumption that the proportion of field sizes from 0.5-2 ha decreases as farm size increases.
- Any allocation reflects the assumption that the proportion of field sizes great than 100 ha increases as farm size increases from 100 ha upwards.

From the tables relating field sizes to farm sizes for different countries and regions, we then developed matrices of relative proportions which were used to allocate all the fields of a certain size to farms of different size. Spatially explicit national agricultural production data were then filtered through this field-size / farm-size matrix, resulting in production data being allocated to different farm sizes. We did this allocation on the basis of production rather than area, given that there are substantial differences between different agricultural production data sets in relation to actual areas cropped. To take some account of the differences in agro-ecological suitability within a country, we utilised a length of growing period dataset (Jones and Thornton 2009, 2013) to define the following five categories: LGP<60 days, 60-120 days, 120-180 days, 180-240 days, and >240 days per year. For each commodity, we calculated relative production per pixel. Each country's total production of a crop was then allocated by plot size, by farm size and by LGP zone, in relation to the ratio of relative production to relative area. This final step was done to take some account of areas with more or less suitability for the production of each commodity, as reflected in the production data; this results in a weighting of field sizes according to their relative production as spread across the country's farm sizes. This is an important element, because the methods we used do not allow us to say where farms of particular size are actually located; and a small farm in a low rainfall regime will not be as productive as a small farm in a higher rainfall regime, all other things being equal. Our estimates of farm-size distributions in countries where such data do not exist are plausible, but they would benefit from triangulation from other sources. A fully spatially-explicit farm size distribution dataset for the globe is yet to be developed.

An example of the calculation procedure is shown in Table 1. Relative production by plot size and by LGP zone is shown in Table 1A; this shows the proportion of national production of a crop broken down by plot size and by LGP zone. In this example, there are no pixels in LGP zones 4 or 5 and no pixels with a plot size > 100 ha. The proportion of national crop area is calculated on the same basis (results not shown in Table 1). Table 1B shows the allocation of plot sizes to farm sizes. Rows sum to unity, and the grey cells must be zero by definition. In the example, very small plot sizes are allocated to farm sizes as shown; thus 80 percent of the very small plots (<0.5 ha) are allocated to farm sizes < 1 ha, as are 20 percent of the small plots (0.5-2 ha). The distributions by plot size (down the column) follow the three rules given above. The allocation was done by trial-and-error so that the relative total area of each plot size category, as calculated across all farm sizes, matches the relative area of each plot size category calculated from the dataset of Fritz et al. (2015) for the country under consideration (data not shown in Table 1). The third step in the procedure is shown in Table 1C, where the relative production RP of the crop in plot size *i* and farm size *j* is calculated as:

$$RP_{i,j} = \left( \sum_{k=1}^5 PROD_{i,k} / AREA_{i,k} \right) * FA_{i,k}$$

where *k* is the LGP zone, PROD is the proportion of national production (Table 1A), AREA is the proportion of national area, and FA is the imputed plot size proportion (Table 1B). These values of RP are then summed for each farm size and normalised to match total national production of the crop (columns 6 and 7 in Table 1C).

Table 1.

A. Relative production by plot size (Fritz et al., 2015) and LGP zone (Jones and Thornton, 2013).

Relative Production	LGP 1 (<60 days)	LGP 2 (60- 120)	LGP 3 (120- 180)	LGP 4 (180-240)
Plot size 1 (<0.5 ha)	0.210	0.050	0.000	0.000
Plot size 2 (0.5-2 ha)	0.080	0.230	0.280	0.000
Plot size 3 (2-100 ha)	0.000	0.150	0.000	0.000
Plot size 4 (>100 ha)	0.000	0.000	0.000	0.000

B. Imputed allocation of plot sizes to farm sizes (see text). Grey cells must be zero by definition.

<b>Plot size by farm size matrix</b>	<b>Plot size 1 (&lt;0.5 ha)</b>	<b>Plot size 2 (0.5-2 ha)</b>	<b>Plot size 3 (2-100 ha)</b>	<b>Plot size 4 (&gt;100 ha)</b>
Farm size < 1 ha	0.80	0.20	0.00	0.00
Farm size 1-2 ha	0.55	0.45	0.00	0.00
Farm size 2-5 ha	0.20	0.50	0.30	0.00

C. Relative production (from A above) allocated to the plot size by farm size matrix (B above).

<b>Plot size by farm size matrix</b>	<b>Plot size 1 (&lt;0.5 ha)</b>	<b>Plot size 2 (0.5-2 ha)</b>	<b>Plot size 3 (2-100 ha)</b>	<b>Plot size 4 (&gt;100 ha)</b>	<b>Production by farm size (sum)</b>	<b>Normalised production by farm size</b>
Farm size < 1 ha	0.883	0.804	0.000	0.000	1.687	0.245
Farm size 1-2 ha	0.607	1.809	0.000	0.000	2.416	0.351
Farm size 2-5 ha	0.221	2.010	0.540	0.000	2.771	0.403
<b>Total</b>					<b>6.874</b>	<b>1.000</b>

**Crop production data:** The majority of the EarthStat crop production data used here was developed for year 2000 (Monfreda et al, 2008), with updates for major crops (wheat, rice, maize, soy) to year 2005 (Ray et al, 2012). The yield and harvested area data for the year 2000 were derived as an average of crop census data from 1997-2003. A range of years was used because census data are not reported every year. In addition, the average reduces anomalies from short-term weather and market shocks. Census data were used from 206 countries, 150 of which had sub-national data at the state/province level, 73 of those 150 countries had data at the county/district level.

Monfreda et al. 2008 then combined these crop census data with a cropland area data layer (Ramankutty et al. 2008) to distribute yields and harvested area data within political units. The Ramankutty et al. 2008 cropland area was developed by combining agricultural census data with two satellite-derived land cover products (Friedl et al. 2002, Bartholome et al. 2005). Monfreda et al. 2008 distributed crop-specific harvested area data within political units proportional to total cropland area; yield data were distributed uniformly within political units.

More detailed methods for developing the crop production data are in Monfreda et al. 2008; additional details for the cropland area data are in Ramankutty et al. 2008. Details on the updates to the yield and harvested area data for wheat, rice, maize are available in the supplementary materials of Ray et al. (2012). The data are available at: [www.EarthStat.org](http://www.EarthStat.org)

**Global livestock production:** We updated the global livestock productivity dataset of Herrero et al. (2013) for 2000 to the base year 2005. We made all the calibrations by country rather than by region, hence adding significant additional detail to our estimates. Detailed information of the methods employed for constructing these datasets is presented in Herrero et al (2013). What follows is a summary of the methods.

A livestock systems classification based on an earlier effort by Sere and Steinfeld (1996) and recently updated by Robinson et al (2011) was used as the starting point. We differentiated 8 different types of livestock systems in 28 geographical regions of the world for this study. These are three types of each grazing and mixed systems, differentiated by agroecology: arid, humid and temperate/highland, and peri-urban and other systems. Details can be found in Robinson et al. (2011).

Numbers of animals for each of these systems and regions were estimated using the data of Robinson et al (2014) for the year 2005. For ruminants (cattle, sheep and goats), we disaggregated the dairy and beef cattle herds using livestock demographic data for total cattle, sheep and goats and the dairy females for each species, respectively, from FAOSTAT. We used herd dynamics models parameterised

for each region and production system using reproduction and mortality rates obtained from extensive literature reviews to estimate herd composition. We then subtracted the number of total dairy animals from the total number for each species. This procedure enabled us to have distinct herds for the production of milk and beef.

For monogastrics (pigs and poultry), we only differentiated two systems: smallholder and industrial production systems, since these are the most important ones and industrial systems exhibit most of the growth in meat production globally (Bruinsma 2003) The allocation of poultry, eggs and pork production was done on the basis of knowledge of the total product output from these two systems from national information from selected countries in the different regions, applied to the respective region. The numbers of animals contributing to the estimated animal production was also computed using herd dynamics models coupled with information on mortalities, reproduction and productivity for these two main systems for each region.

The calculations of biomass consumption and productivity estimations from different species in each region and system followed several stages. We first developed feasible diets for each species in each region and production system. The proportions of each feed in the diet of each species was obtained from extensive information available in the literature and from databases and feeding practice surveys at key research centres in the world (i.e. FAO, ILRI, NDDDB). Data on feed quality was obtained from the databases containing regional feed composition data for each feed. We then estimated productivity. For ruminants, the information on the quantity and quality of the different feeds was then used to parameterise an IPCC tier 3 digestion and metabolism model (RUMINANT, Herrero et al 2002), as described in Herrero et al (2013) The model estimated productivity (milk, meat), methane emissions and manure and N excretion. For monogastrics, information on feed quality was used to estimate feed intake, productivity and feed use efficiency using standard nutrient requirements guidelines (NRC 2008).

All information on animal production (bovine milk, bovine meat, sheep and goat milk, sheep and goat meat, pork, poultry and eggs) and for grains as feed was harmonised with FAOSTAT's commodity balance sheets at national level following an iterative procedure restricted to deviate +/- 20% from the statistical data in FAOSTAT. More information of this process can be obtained in the supplementary information and in Havlik et al. (2013).

**Fish production data and maps:** Landings of marine and freshwater fishes, both wild caught and aquaculture production was mapped to 30-min spatial cells. Marine capture fisheries data was sourced from <http://dx.doi.org/10.4226/77/58293083b0515> and this represents a harmonized and mapped compilation of global catch from 1950 to 2014 sourced in turn from the United Nations Food and Agriculture Organization's (FAO) Capture Production 1950-2014 dataset (Release date: March 2016 [www.fao.org](http://www.fao.org)), International Committee for the Exploration of the Sea (ICES) 1950-2014 ([www.ices.dk](http://www.ices.dk)), Northwest Atlantic Fisheries Organisation (NAFO) Catch and Effort 1960-2014 ([www.nafo.int](http://www.nafo.int)), Southeast Atlantic (SEAFO) Capture Production 1975-2014 (Release date: June 2016) ([www.seafo.org](http://www.seafo.org)), General Fisheries Commission for the Mediterranean (GFCM) Capture production 1970-2014 (Release date: April 2016) ([www.gfcm.org](http://www.gfcm.org)), Fishery Committee for the Eastern Central Atlantic (ECAF) Capture production 1970-2014 (Release date: May 2016) ([www.fao.org/fishery/rfb/ecaf](http://www.fao.org/fishery/rfb/ecaf)), Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR) Statistical Bulletin 2016 Vol. 28 1970-2014 ([www.ccamlr.org](http://www.ccamlr.org)) and Sea Around Us project (SAUP) – records for FAO area 18 (Arctic) v1 1950 TO 2010 (extrapolated to 2014) ([www.searroundus.org](http://www.searroundus.org)). See description in <sup>1,2</sup>(and references therein) for fuller details of marine data treatment.

Aquaculture was sourced from FAO (Aquaculture Production (Quantities and values) 1950-2014 (Release date: March 2016 [www.fao.org](http://www.fao.org)). Marine and brackish species aquaculture production was mapped to the reporting country's coastal cells equally. Both freshwater capture (from FAO capture sources) and freshwater species aquaculture production (from FAO's aquaculture source) were mapped to spatial cells within the reporting country which contained lakes, reservoirs or permanent rivers (codes 1-4 inclusive from the Global Lakes and Wetlands Database GLWD Level 3)<sup>3</sup>. Each reported tonnage was mapped equally to candidate cells.

**Nutrient composition and nutrient requirements:** The quantity of specific nutrients needed from the diet varies according to physiological requirements that vary by age, gender and for women, whether they are pregnant or lactating, and the extent to which a nutrient is utilized by the body, also known as

bioavailability. Where possible, we use the Recommended Dietary Allowance (RDA) which represents the average intake that would meet the needs of 97.5 percent of healthy individuals in a group. Where an RDA was not available for certain nutrients or population groups, we used Adequate Intake (AI), which is the level of intake assumed to be adequate for healthy individuals.

The measures used in this paper were developed by the US Institute of Medicine (*I*).

The nutrient requirements used in this paper are for a representative consumer, weighting each age and gender group by its population. We used the baseline population estimates for Shared Socioeconomic Pathway 2 (Fricko et al. 2016). The SSP population data set does not include the number of pregnant and lactating women so these were estimated by assuming that each is 20 percent of the number of children in the age group 0 to 4.

**Calculation of diversity metrics:** We calculated three diversity metrics based on all crop, livestock and fish products used in the analysis (Remans et al., 2014):

1. the Shannon diversity index, H, which reflects how many different types of foods are produced in a pixel, and how evenly these different types are distributed;
2. The species richness, S, a simple count of the number of commodities produced in each pixel;
3. the Modified Functional Attribute Diversity index (MFAD), the sum of pairwise distances between functional units in terms of nutrient composition for calcium, folate, iron, protein, vitamin A, vitamin B12 , zinc. This reflects the diversity in nutrient composition of foods produced in each pixel .

Shannon diversity metric (H)

$$H = \sum_{i=1}^S - (P_i * \ln P_i)$$

Where:

H = the Shannon diversity index

P<sub>i</sub> = fraction of the entire population made up of species i

S = numbers of species encountered

Modified Functional Attribute Diversity (MFAD)

$$MFAD = \frac{\sum_{i=1}^S \sum_{j=1}^S d_{ij}}{N}$$

Where:

MFAD = Modified Functional Attribute Diversity

d<sub>ij</sub> = Euclidean distance between functional traits of species

S = numbers of species encountered

Σ = sum from species 1 to species S

N=total number of # functional units
