Erokhin, D., & Zagler, M. (2023). Explaining and Predicting Double Tax Treaty Formation with Machine Learning Algorithms. *WU International Taxation Research Paper Series*, (2023-03).

# Content

Introduction

Data and methodology

Results

Conclusion

# Tax treaty formation

- Main goals of tax treaties:
  - Boost **trade and investment** by eliminating tax barriers;
  - Fight tax evasion and double non-taxation with **anti-avoidance** measures;
  - **Exchange of information**, a primary focus of new tax treaties.
- **Complex decision-making process** precedes tax treaty formation:
  - Historically driven by “**chess-games between superpowers**”, **key persons' decisions, and corporate lobbyism**;
  - **Policy diffusion** and other factors may influence tax treaty formation.
- Double tax treaty probability can be predicted using machine learning approach.
- Highly relevant for policymakers:
  - Identifies advantageous treaties to pursue given **limited capacity of negotiators**;
  - Helps **assess risk of FDI diversion** to neighboring jurisdictions;
  - Aids in understanding level playing field for multinational firms in foreign markets.

# Literature – tax treaty formation

## **Economic factors:**

- Personal tax rates, non-resident withholding tax rates on dividends and interest
- FDI stock, symmetric allocation of FDI
- Transfer price, auditing costs, production costs
- Revenue sharing differences

## **Governance and policy factors:**

- Tax haven bargaining power
- Good governance
- Experience in entering into tax treaties

## **International relations factors:**

- Spatial spillovers and dependence in tax treaty formation

- Export-product competitors
- Power asymmetries between signatories
- Developed countries compensating developing countries' tax base losses through foreign aid

## **Other factors:**

- Common language
- Information sharing, tax audit, and revenue sharing agreements

## **Withholding tax rates:**

- Positive relationship with withholding tax rates negotiated in past tax treaties
- Spatial dependence of dividends withholding tax rates
- Increase in withholding tax rates with asymmetric FDI activities

# Machine learning in economics

- Increased application in recent years.
- Various areas of economics such as energy economics, growth economics, crypto economics, urban economics, and taxation.
- Modeling **complex and flexible relationships**.
- Uncovering **generalizable patterns** and finding functions with high **out-of-sample predictive power**, which is important for policy makers.
- Limited prior theoretical assumptions or major assumptions on variable distribution.

"Machine learning" economics searches on Google scholar

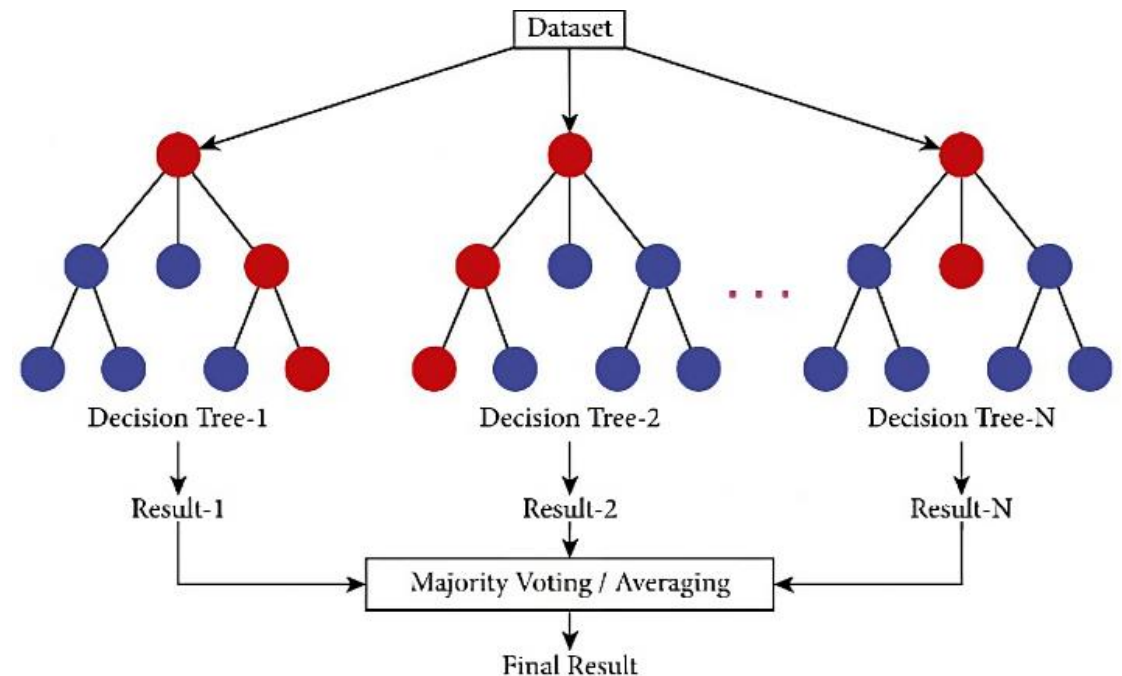

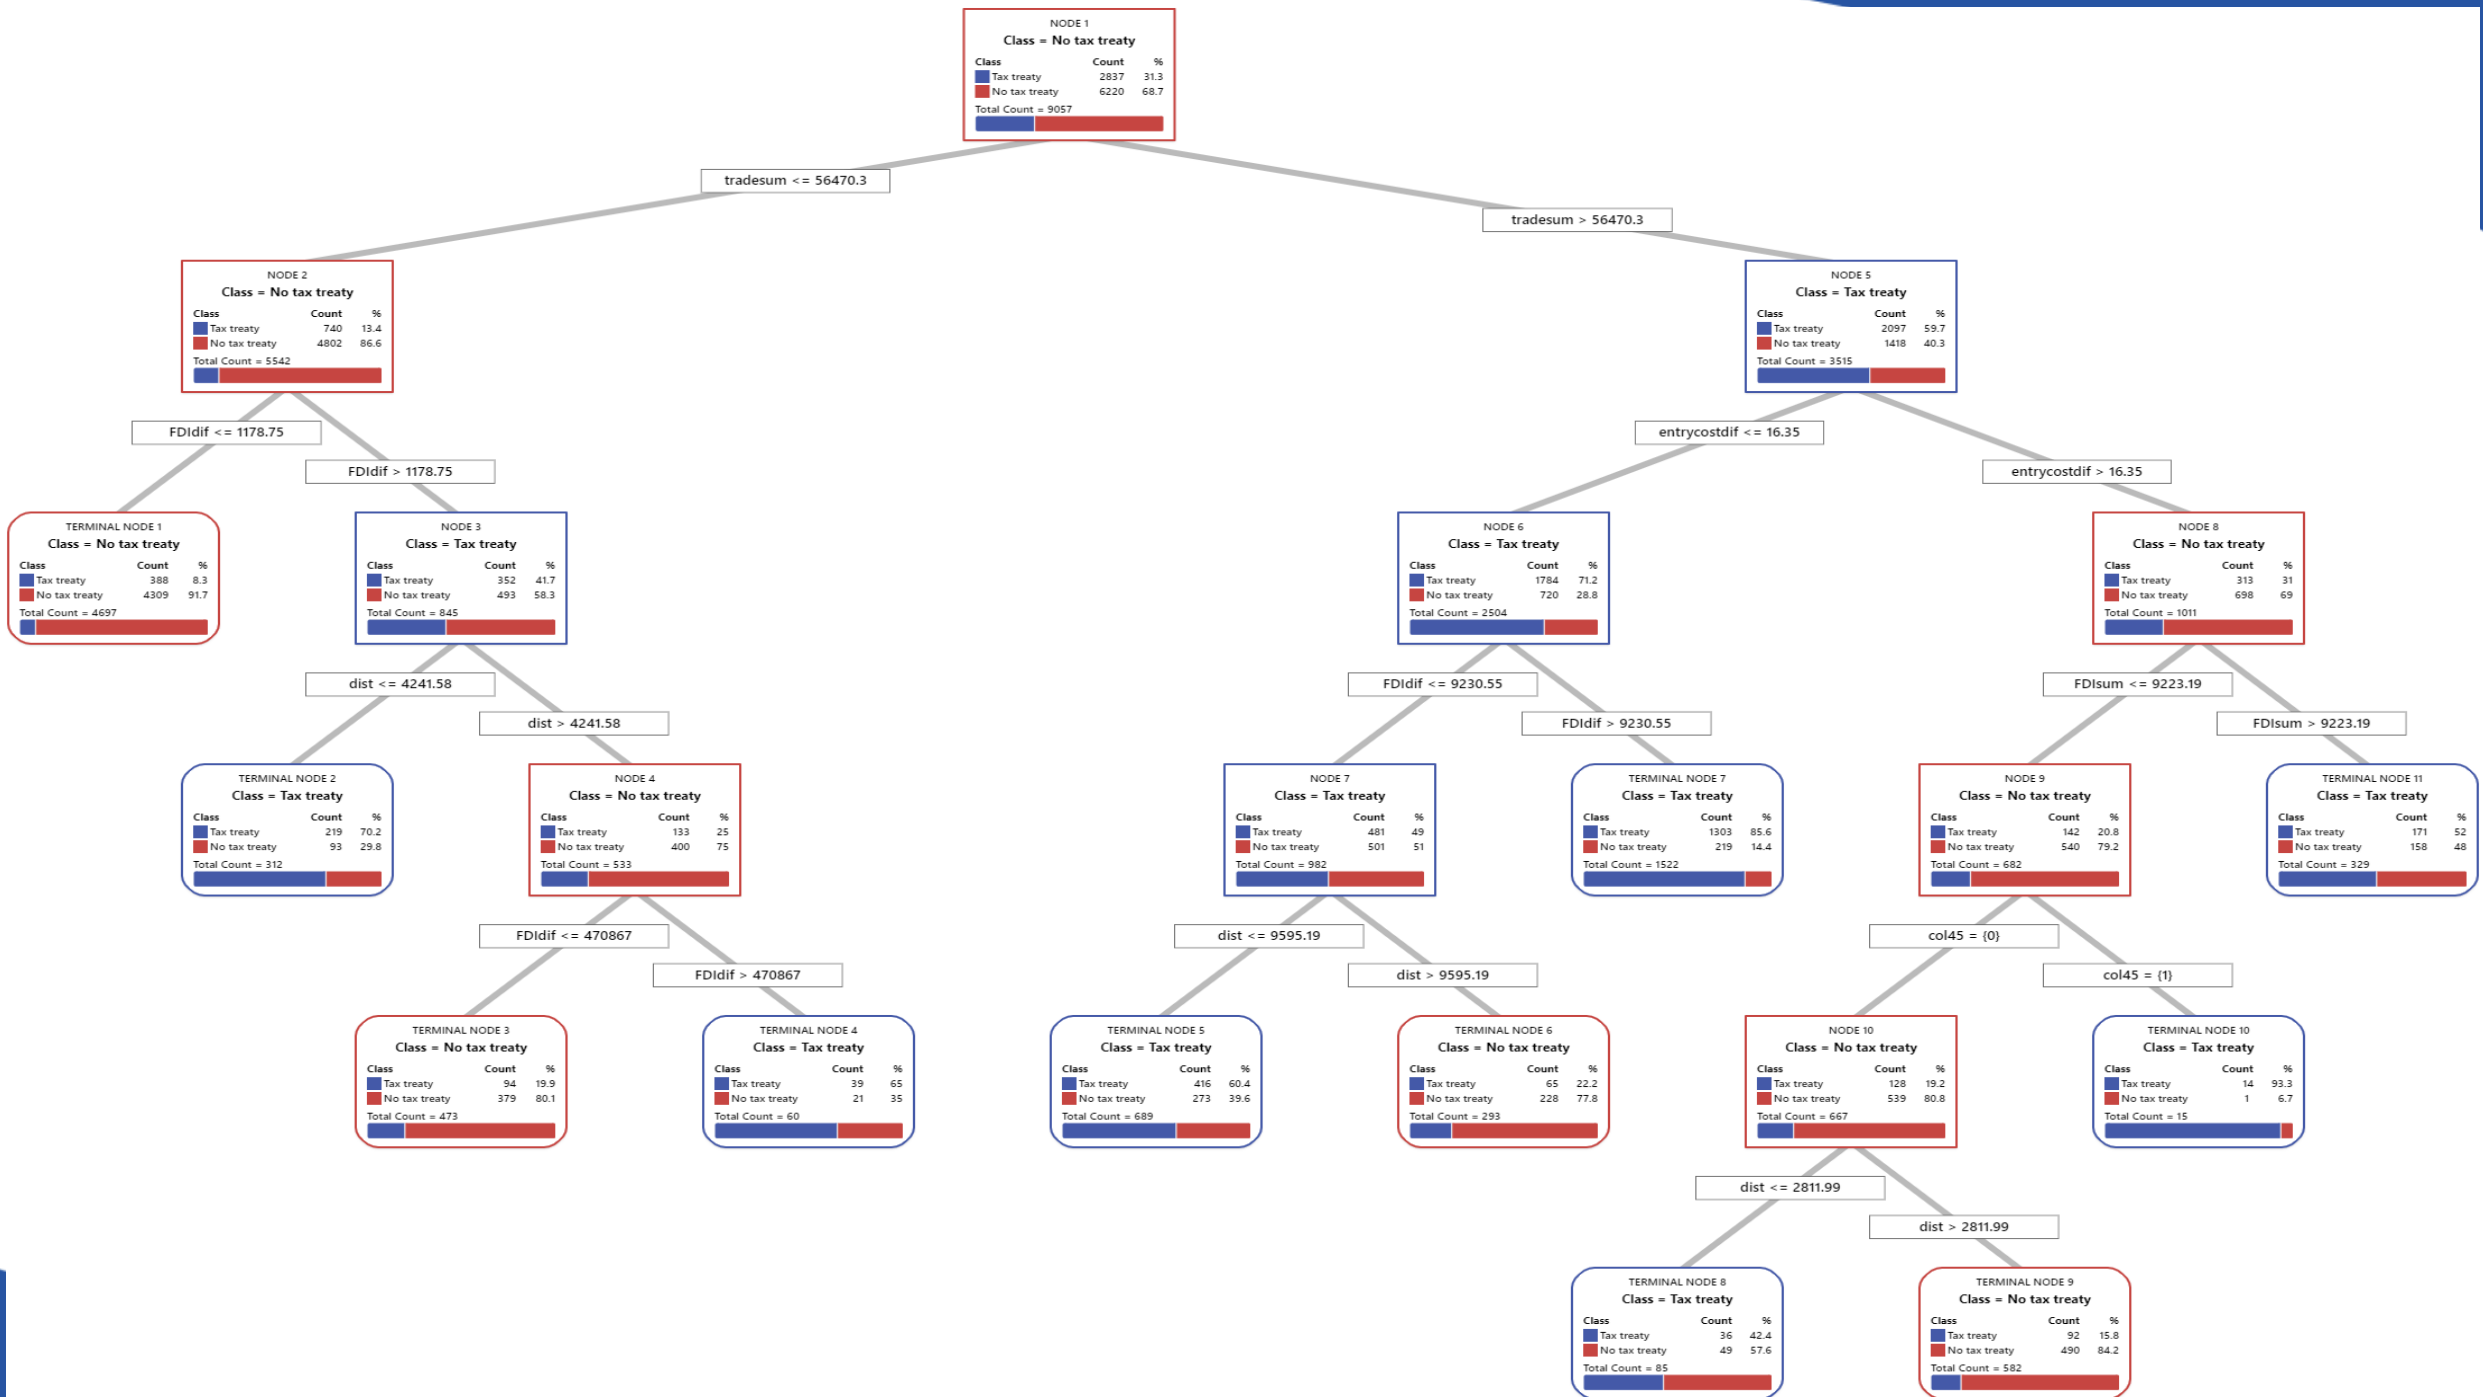

# Methodology and data

- **Binary classification problem:** country pairs as “having tax treaties” or “not having tax treaties”.
- `c_ml_stata_cv` command, Stata/Python integration, scikit-learn API.
- Supervised machine learning algorithms: classification tree, random forest, boosting, regularized multinomial, nearest neighbor, neural network, naive Bayes, support vector machine, and standard multinomial algorithms.
- Classification error rate on the test data, sensitivity, precision, specificity, F1-score, and area-under-the-curve.
- Two periods: 2018 for training the machine and 2019 for testing it.
- 2800 country pairs with tax treaties and 6200 without tax treaties.
- 29 gravity features constructed as bilateral variables.

# Algorithm selection

- The selection of the most accurate algorithm is based on the testing classification error rate, and the **random forest** algorithm has the lowest rate (0.057).
- The random forest algorithm outperforms other algorithms according to all the evaluation metrics.
- Both the random forest algorithm and the classification tree algorithm exhibit a zero training classification error rate and the lowest two testing classification error rates.
- A specific classification tree with 11 nodes drawn using the CART® Classification of the Minitab statistics package.

**NODE 1**  
Class = No tax treaty

# Relative variable importance (random forest)

# Prediction accuracy

# Tax treaty formation prediction

- **59 country pairs** likely to have tax treaties based on 2019 gravity features.
- Germany (9), Saudi Arabia (8), Brazil (7), Myanmar (7), and Hong Kong (6).
- 24 country pairs in negotiation process, 4 signed a tax treaty, 3 initialed a tax treaty, 6 signed or negotiating exchange of information agreement or transport tax treaty, and 3 terminated tax treaties.

Country/region A	Country/region B	Predicted probability of a tax treaty in 2019	Current status of a tax treaty in 2023 (IBFD, 2023; Orbitax, 2023)
Croatia	United States	0.62	Signed (December 2022)
Denmark	France	0.81	Signed (February 2022)
Brazil	United Kingdom	0.76	Signed (November 2022)
Brazil	Poland	0.67	Signed (September 2022)
<b>Austria</b>	<b>Bangladesh</b>	<b>0.55</b>	

## Austria and Bangladesh Seek to Conclude Tax Treaty

May 1, 2024

# Predicted probability vs actual status after 2019

# Implications for parliaments

- Clear **guideline** on how machine learning algorithms can inform policymakers on treaty policy to follow.
- Policymakers in countries with missed opportunities for negotiation should take advantage of **potential treaties** to improve their treaty policy.
- **Neighboring countries** should check their existing treaty network and tax policy with respect to potential partners of their neighbors, given predicted treaties between other countries.
- Other potential applications:
  - Predictive analysis of policy outcomes
  - Economic forecasting
  - Analyzing public opinion
  - Resource allocation
  - Fraud detection
  - ...
