Foreword

IIASA, the Russian Academy of Sciences, and the Russian Federal Forest Service, in agreement with the Russian Ministry of the Environment and Natural Resources, signed agreements in 1992 and 1994 to carry out a large-scale study on the Russian forest sector. The overall objective of the study is to focus on policy options that would encourage sustainable development of the sector. The goals are to assess the forest resources, forest industries, and infrastructure; to examine the forests' economic, social and biospheric functions; with these functions in mind, to identify possible pathways for their sustainable development; and to translate these pathways into policy options for Russian and international agencies.

The first phase of the study concentrated on the generation of extensive and consistent databases of the total forest sector of Siberia and Russia.

In its second phase, the study has encompassed assessment studies of the greenhouse gas balances, forest resources and forest utilization, biodiversity and landscapes, non-wood products and functions, environmental status, transportation infrastructure, forest industry and markets, and socio-economics.

This report, carried out by Prof. Shvidenko, Dr. Samarskaia, Dr. Venevsky and Prof. Nilsson of the study's core team, is a contribution to the analyses of the topics of greenhouse gas balances and forest resources, and forest utilization.

Models for Growth of Pine Stands in Territories of Northern Eurasia

*A.Shvidenko, E.Samarskaia, S.Venevsky
and S.Nilsson*

1. Introduction

Pine is often called the national tree of Russia. Forests with Pine (*Pinus sylvestris*; there also exist seven other Pine species of genera *Pine* which establish natural stands in Russia, but cover less than 1% of all Pine forests) are the second most distributed forest formations in Russia after Larch. Pine forests cover 16% of the Forested Area and have 20% of the growing stock of all Russian forests; corresponding figures for all coniferous forests are 23% and 25% respectively. On a global scale, Russian Pine forests make up about 35% of all Pine forests.

In addition to the large extent of Pine forests, there are several other features of the species which define a significant role in any resource or ecological estimate of the Russian forests. Firstly, Pine forests are widely distributed in densely populated areas (contrary to Larch stands) with a developed infrastructure. Secondly, Pine wood, due to its excellent physical properties and wide distribution in early populated areas, was historically and is currently the most used tree species in Russia. Thirdly, Pine is a species with an extreme adaptability to soil fertility, is quite tolerant to water availability, and is one of the main forest forming species in forest steppe and even steppe regions, where protective functions of forests are of extremely high importance.

This Working Paper has the following main tasks:

- to develop a relevant regionalization of Pine forests with respect to homogeneity of stand growth and dynamic regularities;
- to select relevant existing Russian yield tables, different dynamic models, and data for modeling the growth and productivity of Pine forests;
- to develop a framework of regional models to estimate the dynamics and productivity of Pine stands;
- to prepare yield and growth tables for further examination and validation in Russia;

- to estimate, at an aggregated level, basic indicators for productivity of Pine stands, such as gross growth, net growth and mortality.

2. Short Description of Russian Pine Stands

Pine forests are distributed practically over all the Russian territory which is suitable for forest growth (Figure 1, showing regions for forest taxation of Pine forests in Russia): from sparse taiga (excluding regions of Northern East Siberia) to forest steppe (islands of Pine stands are located in the steppe zone). Pine generates a typical intrazonal forest formation. Forested areas (closed forests) in Russia covered by Pine forests comprise 114 million ha with a growing stock of 14636 million m³ (data for forests managed by state forest authorities by January 1, 1993, FSFMR 1995). The share of Pine forests in the European-Ural part is higher (40 million ha forested area with 4816 million m³ of growing stock comprise 29% respectively 28% of forests in the European part) than in the Asian part (forested area 74 million ha, with a growing stock of 9820 million m³, or 13% respectively 18% of the forests in Asian Russia).

Pine forests have been investigated in Russia for many years, and there are many publications describing forest formations of Pine (e.g., Tjurin, 1952; Shukov, 1961-1965). Below we briefly considered a few features dealing with the needs to model the growth and dynamics of Pine forests.

Covering vast areas with significantly different climatic and soil conditions, Pine forests vary by forest types, species composition, productivity, morphological structure, types of age structure, disturbance regimes, regularities of natural successions, etc. From a topological point of view, Pine forests of large areas are usually divided into *groups of forest types*. For instance, for the European part (along the gradient of increased humidity) there is the *lichen* group of forest types, *clusterberry* (with *Vaccinium vitis-idaea*), *bilberry* (with *Vaccinium myrtillus*), *shamrock* (with *Oxalis acetosella*), *long-mosses*, *sphagnum* and *grasses-bog* groups of forests. The most productive forests are located in the middle of this grouping (e.g., mature shamrock Pine forests have a growing stock of about 500-600 m³/ha while the sphagnum types only have a growing stock of 100-150m³/ha). For the North-Eastern edge of the Pine area (Southern Jakutia), 4 basic groups have been identified: *lichen-Arctostaphylos* Pine stands (dry sites), *clusterberry* (medium humidity sites), *marsh-tea-bilberry* (wet sites) and *sphagnum* Pine stands (bogged areas), (Sherbakov, 1975).

Pine forest types can be indigenous and derivative. After harvesting and fires, Pine usually regenerates quite well, although on reach sites the species can be replaced by soft deciduous species (Aspen and Birch). Postfire derivative Pine successions are common in some types of Spruce and Larch indigenous sites of middle and southern taiga subzones.

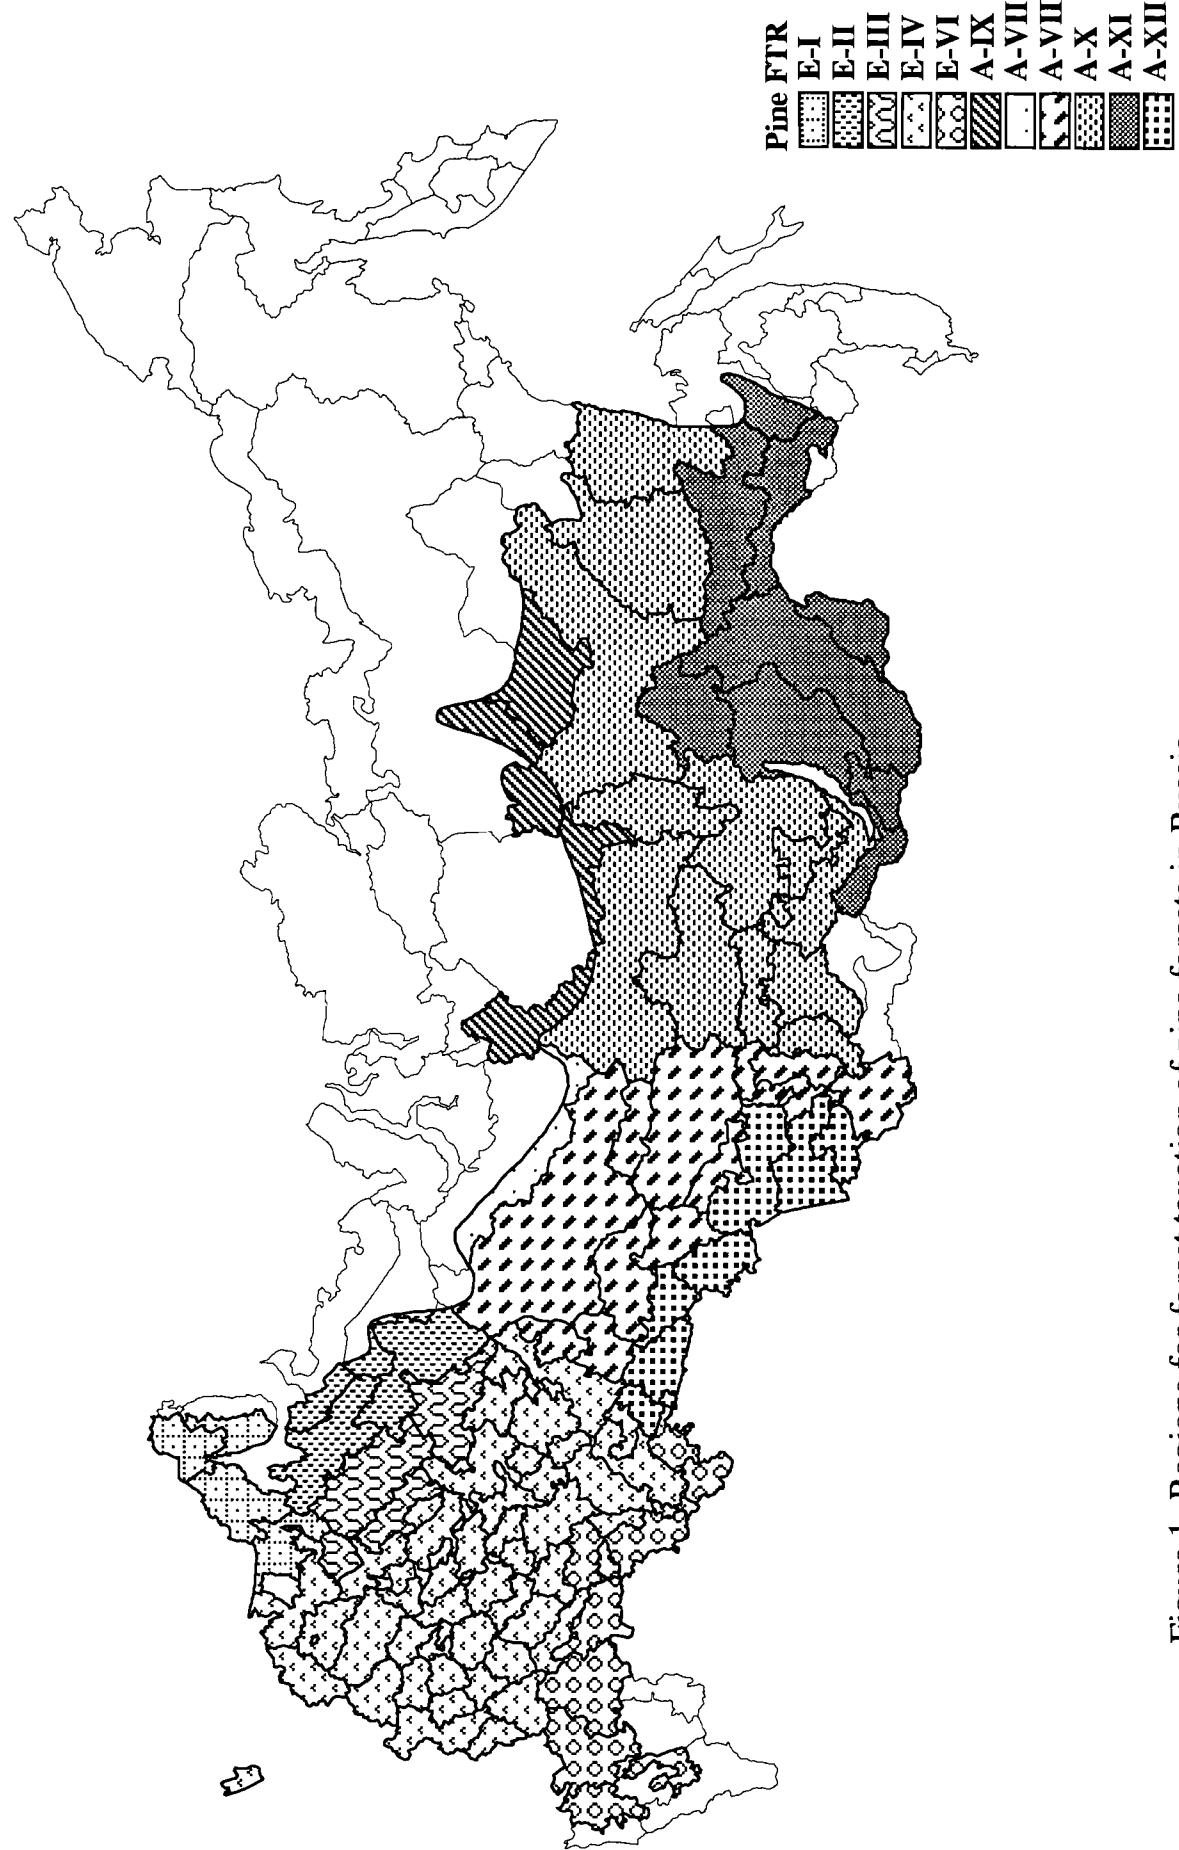

Figure 1. Regions for forest taxation of pine forests in Russia.

The actual productivity of Pine forests depends upon climatic and soil conditions. In major regions of the European Northern part, Siberia and Far East regimes of disturbances (such as fire and insects) can play a crucial role. Potential productivity can be characterized by an average site index (the Russian classification of site indexes use average height and average age of stands as indicators). Examples of such productivity estimates are presented in Table 1. There is an evident gradient of increased productivity from the north to the south and some decrease from the west to the east, although to some extent masked by mountains.

¹ See footnote to Table 1.

Pine stands are represented by different categories of types of age structure (for types of age structure definitions (TASS) see Shvidenko et. al., 1996a). A major part of Pine forests in the European part of Russia is presented by evenaged stands. In the north alone, unevenaged stands comprise up to 20-30% of forested areas. On the contrary, Asian Pine forests are mostly unevenaged (Table 3). The driving forces for the development of unevenaged stands in different parts of Pine growing areas are different. In many areas of the European part (the North-Tkachenko, 1911; Tjurin, 1952; Brjansk oblast'-Tjurin, 1952) natural postfire regeneration is rather intensive and, consequently, generates evenaged Pine stands. But regular forest fires (with a stable average interval of 12-15 to 150-200 years are dependent on landscape properties) which are usually not completely stand replacing disturbances generate a significant part of unevenaged stands. In some forest types of Siberia, a slow intensity of regeneration and formation of stand canopy is an additional reason for the development of unevenaged stands.

Table 3. Distribution of areas of immature, mature and overmature Pine forests by types of age stand structures (TASS).

Zones and subzones	Distribution of Pine forests by TASS (% of forested areas)							
	In European part				In Asian part

¹⁾ EVA - Evenaged Stands; RUE - Relative Unevenaged stands; UEV - Unevenaged stands; GUE - Gradually Unevenaged stands.

Note: Aggregated estimates given in Table 3 are based on available publications and evaluations by regional experts as well.

3. Methods and Approaches. Regionalization of Growth Peculiarities of Pine Stands in Russia

Models for the Pine stands were developed as a part of a modeling system (MS) developed to evaluate the dynamics and productivity of Russian forests. The general description of the MS is presented in Shvidenko et. al. (1996a), and some specific types of models in Shvidenko et. al. (1996b). Normative and model concepts of the MS is generated by unified models of growth and productivity of stands of main forest forming species using all available reference and experimental information, which have been collected during the last decades in Russia, as well as in adjoining states including different types of yield tables (general and regional; normal and modal, i.e., actual stands, single-species and mixed stands, etc.), different models and tables of gross and net growth, results of measurements on permanent sample plots, etc.

With respect to the model development, the following basic approaches have been used in the modeling system (MS).

1. The dominating type of models used in the MS is regional models for actual stands (*models for modal stands*). This type of model has an evident advantage as it describes the average features of stand growth in a specific region taking into account actual species composition, peculiarities of growth, type of age stand structures, etc. The basic shortcoming of this model type is the close dependence of regimes of anthropogenic and natural disturbances which formed the stands historically, i.e. these models reflect the stand development by a historical development for a specific period. If the growing conditions change, the models become inadequate. Changes of forest fire regimes in natural forests of Siberia due to improved fire protection or changes of thinning intensity in managed forests are examples of possible systematic errors generated by such models. Nevertheless, regimes of disturbances for many large regions of the taiga zone were rather stable during the last 20-30 years when the major part of the data used for the MS development were collected.
2. Unfortunately, models for modal stands can not be developed for a significant part of areas of Pine forests (specifically in Siberia and Far East) due to a lack of initial data. An aggregation of the approach mentioned above is the development of models of productivity of stands with variable growing stock, which present age dynamics of gross and net growth for stands over site indexes and different stocking levels. Such models have been developed for Pine stands, together with

other main forest forming species, and are presented in Shvidenko et al. (1996b). We only emphasize here that such types of models present average values of indicators by a definite age and stocking level independently of the stand's previous history. Thus, they can only be used for estimates of averages for a large number of estimated stands. Validation of such models for a number of regions has shown that the models give fairly accurate results for a separate stand if a) the stand is evenaged, and b) if the relative stocking of the stand has not changed significantly during its development.

3. Two types of models for fully stocked (or *normal*) stands were included in the MS: regional and general. The practical use of these models are 1) to define the relative stocking of actual stands, 2) to use them if the modal stand models are not available.
4. Finally, some specific types of models could be developed for a specific species for practical needs, e.g., models for forest plantations, models for mixed or unevenaged stands, models for some specific ecological conditions, etc.
5. The models used were unified as much as possible and kept as simple as possible. As a base model, the modified Richard-Chapman growth function was used for the description of dynamics for 5 basic indicators of forest stands (average height H and diameter D , basal area BA , growing stock (i.e., total stemwood volume of all living trees at age A) GS , and total productivity or total volume (i.e., all stemwood produced by a stand during the period from its origin to age A) TV . For instance, the model for GS is

$$GS = c_1 (1 - \exp(-c_2 A))^{c_3}, \quad (1)$$

where the coefficient c_1 is the maximum value of the growth function (the asymptote), $c_1 c_2 (1 - 1/c_3)^{(c_3 - c_1)}$ is the maximum of the current increment of the indicator described by function (1), and $\ln(c_3)$ is the turning point of the growth function. Function (1) describes the growing phase, i.e., when an indicator being modeled strongly increases. In a modified form (Venevsky and Shvidenko, 1996), that is designated to characterize both growing and the destructive phases (e.g., for such indicators as basal area and growing stock which can decrease after the age of maturity, or after impacts of some types of disturbances), the growth coefficient c_2 depends on age:

$$c_2 = \text{const, if } A < Ad,$$

$$c_2 = c_2 * \exp(-c_4 (A - Ad)), \text{ if } A > Ad,$$

where A_d is the age when destruction (decrease of the indicator) starts. Such an approach assumes that the velocity of growth is exponentially decreasing from the beginning of the destructive phase. The derivatives of the basic indicators mentioned above present the current increment (e.g., dGS and dTV are net respectively gross growth, i.e., basic indicators of current productivity of forests).

6. The major part of the Russian tables and models of forest dynamics was established by using two basic classifiers: site index (different numerical indicators for the definition of a site index were used) and forest type. In this respect, we will not elaborate on the many discussions which took place in Russia during 1920-1980 (e.g., see reviews in Orlov, 1925; Tretjakov, 1927; Nikitin, 1966; Kozlovsky and Pavlov, 1967; Svalov, 1979; Anuchin, 1984), but will only list the main conditions used for the unified classifiers of the site index defined by Orlov (1925):

- forest type in current Russian classifications does not have any strong quantitative definitions;
- within the limits of a single forest type (the initial unit of classification used by the Russian forest inventory) there could be up to 3-4 site index classes;
- for all tables developed over forest types, the recalculation in the models of the site index system gave satisfactory results if the limits for ecological modifications of the forest formation were provided (e.g., automorphic and hydromorphic);
- all quantitative applications of forest inventory data and a major part of forest management in Russia are based on site index classifications;
- State Forest Account data, which is the single source of aggregated data for Russian forests does not include any quantitative data on forest types.

It should be pointed out that the general site index developed by Orlov (1925) is only used as a classifier for a specific age (as a rule 100 years), while the dynamics in the models use initial data.

7. The territorial (spatial) distribution of the models and the algorithm for the usage of the MS play a crucial role in the reliability and accuracy of all applications.

Russian forest science historically paid great attention to different types of natural regionalizations due to the huge territory and large diversity of the Russian forests. The forest inventory regionalization (FIR) is a partition of the forest territory, based on homogeneity of growth, structure and quality of stands (Sagreev, 1978). It is

assumed that within a specific FIR region, the same yield tables and growth models could be applied with sufficient accuracy. In order to identify the FIRs, different principles and criteria were used: climatic indicators in combination with productivity of the main forest forming species (Gorev, 1968; Rubtsov, 1970; Voropanov, 1970a; Lositskiy, 1971), different biometric indicators such as the “indicator of normality” D/H or H/D (D and H-average diameter and height of a stand respectively), Schiffel’s indicator (N/D, N-number of stems per ha), “life potential indicators” $Z_{\text{cur}}/Z_{\text{ave}}$, where Z_{cur} and Z_{ave} are current and average increment respectively, etc. (Voropanov, 1970b; Krest’jashin et al., 1971). Sagreev (1978) provided detailed analyses of growth regularities of Pine stands (basically in the European part of the former Soviet Union) and recommended as a basic criterion for the identification of FIRs the change of site index class and the intensity of growth (growth type by height; Seide, 1968). He divided the Pine forest area of the European part of the former Soviet Union into four regions, based on differences in growth peculiarities, from which three cover the Russian territory (see Figure 1):

Region II (by Sagreev, 1978)—Pine stands with good growth, divided into two subregions (the second subregion closely follows the southern boundary of the natural area of pine distribution as this part has smaller productivity). Generally, Pine stands in region I have a high productivity. Average site index is I.8.

Region III—Pine stands with moderate growth, covers large areas of zones of middle and southern taiga. Basic growing conditions are characterized by some heat deficit under sufficient (sometimes redundant) water availability. Average site index is III.8.

Region IV—Pine stands with low growth, includes Pine forests of the Extreme North (Kol’sky peninsula, Komi Republic), which belong to forest tundra and the northern taiga. The region is characterized by unfavorable conditions for Pine growth due to a significant lack of heat and surplus of humidity. Average site index is IV.7.

Sagreev’s forest inventory regionalization of Pine stands in the European part has a clear geographical basis with similar features for structure and productivity of forests, specifics of forest types, level of anthropogenic changes and successional dynamics. Nevertheless, the approach developed by Sagreev can not be used in many areas of Siberia and the Far East for several reasons. Firstly, forests in these regions are strongly impacted mostly by natural disturbances, which are linked to landscape (geographical) nature. Secondly, large shares of Pine stands are unevenaged.

The general FIR of the FSU which was established during 1975-1990, divided the total territory of Russian forests into 8 forest inventory regions: European North-West, European North-East, European Center and European South, Mountain Ural, Northern Caucasus, Siberia, (continental) Far East, Sakhalin and Kamchatka.

Different approaches were used to divide these regions into subregions based on regularities of growth. For instance, the European North-Eastern region has been divided into 4 subregions for all species (Voinov, 1986) based on a forest vegetational regionalization (Subtundra, Northern Taiga, Middle Taiga and Southern Taiga subregions). For Far Eastern forests the subregions were generated based on separate species: 6 subregions were suggested for Larch, 3 for Spruce and 2 for Cedar (Korjakin, 1990). The forest vegetational regionalization was used as a basis for the FIR division in Siberia (Falaleev et al., 1975).

Within the framework of the developed MS, we followed the following rules of thumb: 1. Primary units of territorial partition (regionalization) should be the same for all basic resources and ecological estimates for different species. 2. The regionalization has to present possibilities to provide different generalizations of both natural and administrative nature. 3. Existing initial data (aggregations) should have a scale which would be compatible with primary units used in the regionalization.

It can be shown that the only relevant division into ecological regions (ecoregions) is a division that completely corresponds to the above requirements. For Russia, 141 ecoregions have been identified: 63 in Siberia and in the Russian Far East, and 78 in European Russia. The following principles have been used for the identification:

1. The basic ecological cycles should be of the same magnitude. A consequence of this is a requirement of the approximate equality of basic indicators for productivity of the terrestrial biota.
2. Ecoregions should be homogeneous with respect to climatic and soil conditions. Mountain areas and plains as well as permafrost and non-permafrost areas should be separated. Consequently, ecoregions should be homogeneous with respect to forest growing potential, basic features of forest cover, and regimes of natural disturbances. It means that basic areas of stands of a specific species should not have much variation in the site indexes.
3. Character and level of anthropogenic and natural disturbances should be similar within an ecoregion. This follows from the requirements that disturbance regimes have to be similar.
4. Ecoregion boundaries should not cross the administrative boundaries of objects of the Russian Federation (oblasts, kraj, and autonomic republics).

From the requirements listed above it can be concluded that an ecoregion can serve as a primary unit for the FIR, but for large scale growth evaluations ecoregions have to be aggregated. Such aggregations can be different for different species and different goals of investigations. For the FIR of Pine stands the following basic requirements were used: a) the minimum difference between the average site index is one class; b) homogeneity of basic groups of forest types, which means species composition, type of age structure, regularities of growth and disturbances regimes; c) areas of Pine stands and availability of initial tables. Finally, we developed 12 forest inventory regions for Pine stands: 6 in European part (index E is given below before the number of ecoregions) and 6 in the Asian part (index A):

- E-I. Western ecoregions of northern and middle taiga (Murmanskaja oblast and Karelia republic).
- E-II. Eastern ecoregions of forest tundra and northern taiga (Arkhangelsk and Vologda oblast, and Komi republic).
- E-III. Ecoregions of middle taiga (Archangelsk, Perm and Vologda oblast, and Komi republic).
- E-IV. Ecoregions of southern taiga, mixed forests, deciduous forests, and forest steppe.
- E-V. Mountain ecoregions of middle and southern taiga of Ural.
- E-VI. Ecoregions of steppe and semidesert zones of the European part.
- A-VII. Ecoregions of sparse taiga and northern taiga of West Siberia.
- A-VIII. Ecorgions of middle and southern taiga of West Siberia.
- A-IX. Ecoregions of sparse taiga and northern taiga of East Siberia and Far East.
- A-X. Ecoregions of middle taiga, southern taiga, subtaiga, and forest steppe of East Siberia and Jakutia.
- A-XI. Mountain taiga ecoregions of Burjatia, Irkutsk, Chita, and Amur oblasts.
- A-XII. Ecoregions of forest steppe and steppe zones of West Siberia.

The distribution of the ecoregions from the suggested FIR regions is presented in Figure 1. For the European part our regions are similar to those recommended by Sagreev (1978).

- 5. Technically, the modeling process was realized in the following way. For a given type of models and groups of ecoregions, basic data were selected. Usually, these were table(s) of model(s) which were validated earlier in Russia. If different tables of the same type were available for a region, a special procedure for comparison of the tables was used, and decisions on which table to use were made on an expert

basis. If the tables (models) had no significant statistical differences, the coefficients of the models were calculated either for all initial data or for the most complete and reliable source. All supplementary information and results of measurements available were also used.

Much research on inventory reference-normatives was carried out from 1970-1990 under the guidance of the former USSR State Forest Committee. Results of this work, after approval by special expert commissions, have been published in a number of regional reference books for the forest inventory (e.g., Moshkalev, 1984; Shvidenko et al., 1987; Voinov, 1986; Korjakin, 1990). Unfortunately, such regional reference books have not been published for the Siberian forests. Nevertheless, the selection of the basic sources was facilitated by the availability of these publications. Data for missing indicators (some initial sources did not report the total productivity) were taken from other relevant publications, archives, and results of measurement.

Due to the fact that a significant part of the initial data used for the model development were presented in the form of organized data, e.g., in the form of yield tables, the required accuracy of approximation was rather high, some 7% for any approximated estimate. The coefficients c_1 , c_2 and c_3 , defined in this way, were used for the development of the models. The models were presented in two-dimensional form (site index and age). To arrange the dependence of coefficients of site indexes, a quadratic regression (Shvidenko et al., 1996a) was used.

$$c_1 = c_{13} N^2 + c_{12} N + c_{11}$$

$$c_2 = c_{23} N^2 + c_{22} N + c_{21}$$

$$c_3 = c_{33} N^2 + c_{32} N + c_{31}$$

where N is the number of the site index (1 corresponds to site indexes Ia, 2 to site index I, ..., 6 to site index Va, etc.). If initial sources were developed over forest types, a fractional number of site index as corresponding to a given forest type was used for the calculations of the coefficients.

4. Models

Based on the approaches mentioned above, 22 models are suggested to describe the dynamics of the Pine forests in Russia (the codes presented below are: the first 3 digits is the code of species in the Russian State Forest Account, e.g., 101 Pine; the 4th digit is the type of table: 1 normal general, 2 normal regional; 3 variable stocking; 4 modal; the 5th digit is the type of age structure: 1 evenaged, 2 relatively unevenaged, 3 unevenaged, 4 gradually unevenaged; and the 6th digit is the type of ecological modification: 1 common; 2 automorphic conditions; 3 hydromorphic conditions). A short description of the main basic sources used in the calculations is presented below.

4.1. Models for Fully-Stocked (normal) Stands

101212. Models for goal programs of cultivated plantations of Pine stands. The models are developed for Id, ..., IV site indexes, and covers an age-span from 10 to 120 years. The region for accurate application is E-IV (see Figure 1). The models could be used for long-term predictions in other regions, excluding regions of sparse and northern taiga as well as steppe and semi desert zones (Basic source: Strochinsky et al., 1992, pp. 20-27). Authors of the initial tables are A.Strochinsky, A.Shvidenko, and P.Lakida.

101212. Models of Pine plantations. The models are designated for description of the dynamics of artificial (planted) Pine forests in the regions E-IV for Ib, Ia, ..., V, Va site indexes, and cover an age-span from 10 to 120 years. The models can be used for Pine plantations in ecoregions of southern taiga, mixed and deciduous forests, and forest steppe. (Sagreev et al., 1992, pp. 335-337). Author of the initial tables is V.V.Uspensky.

101111. General models. The models can be applied for all evenaged natural Pine stands if regional models for normal stands are absent. The models are recommended for implementation in regional normal stands in ecoregions of southern taiga, mixed forests, deciduous forests and forest steppe zones of the European part of Russia. The models are developed for Ib, Ia,..., Va, Vb site indexes, and cover an age-span from 10 to 200 years (Sagreev et al., 1992, pp. 299-304). Author of the initial tables is V.V.Sagreev.

101212. Models for western ecoregions of northern and middle taiga zones (Karelia and Murmansk oblast, the FIR region E-I). The models are developed for Ia, I, ..., V, Va site indexes, and cover an age-span from 20 to 180 years. (Kozlov, 1985, pp. 64-94). Author of the initial tables is I.F.Kozlov.

101212. Models for forest-tundra and northern taiga ecoregions of the European part of Russia (the FIR region E-II). Developed for II, III, ..., Va, Vb site indexes, and ages from 20 to 300 years including destructive stages (Voinov, 1986, pp. 122-123). Author of the initial tables is V.I.Levin. Total productivity was calculated by the formula $TV = R_i GS$, where $R_i = (R - 0.007SI) (0.9517 + 0.000526 A)$, $R = TVg/GSg$, where TVg and GSg are, total productivity and growing stock respectively of Pine stands given in the general models.

101212. Models for middle-taiga ecoregions of European Russia. Region - E-III. Developed for II, III, ..., Va, Vb site indexes, and ages from 20 to 300 years with destructive phases (Voinov, 1986, pp. 119-122). Author of the initial tables is V.I. Levin. The initial tables have been generated over forest types. The correspondence between forest types and site indexes given by the author is the following: II site index-Pine stands (P.s.) with *Oxalis (kisluchnik)*; III-P.s. with bilberries (*chernichnik*); IV-P.s. with bilberries+long mosses (*chernichnik dolgomoshnij*), P.s. with red bilberry (*brusnichnik*), and P.s. with mosses and lichens (*mokhovo-lishainikovy*); V- P.s. with lichens (*lishainikovy*), P.s. with sphagnum and sphagnum+sedge (*osokovo-sphagnoviy*); Va-P.s. *vakhto-sphagnoviy* and P.s. on bogs. Total productivity is calculated based on regularities in the general models.

101212. Models for mountain ecoregions of middle and southern taiga of the Ural region (E-V). Developed for I, II, III and IV site indexes, and ages from 10 to 160 years. (Verkhunov P.M., 1991, Table 5.6, pp. 213-214). Authors of initial tables are M.I.Galperin and I.F.Korostyljov. Initial tables are generated over forest types.

101212. Models for middle taiga, southern taiga, subtaiga, and forest steppe ecoregions of Central and East Siberia (A-X). Developed by the aggregation of 15 different yield tables for Ia, I, ..., V site indexes, and ages from 20 to 180 years. (Motovilov G.P., 1966; Falaleev E.N. and Polakov V.S., 1969; Falaleev E.N. et al., 1975; Kozlovskiy and Pavlov, 1967). Authors of the initial tables are S.S.Shanin, E.N. Falaleev, E.P.Smolonogov, and E.L.Bessabotnov.

101212. Models for subtaiga, forest steppe and mountain taiga ecoregions of the southern part of West Siberia (A-VIII). Developed as aggregation of 8 yield tables for I, II, ..., Va site indexes, and ages from 20 to 170 years. The authors are the same as above.

101213. Models for northern taiga ecoregions of the West Siberian Plain (A-VII) (hydromorphic conditions). Developed as aggregation of 6 yield tables initially developed over forest types for IV, V, Va and Vb site indexes, and ages from 20 to 250 years (Motovilov, 1966; Falaleev et al., 1975; and Kozlovskiy and Pavlov, 1967).

101212. Models for mountain ecoregions of Zabaikalja (A-XI) (Irkutskaja, Chitinskaja and Amurskaja oblast and Burjatia Republic). Developed for III, IV and V site indexes, and ages from 20 to 250 years (Falaleev et al., 1975; Motovilov, 1966; and Zai et al., 1981).

101212. Models for Pine stands in *melkosopochnik* of Kazakhstan. Recommended for steppe ecoregions of the Urals and West Siberia (A-XII) (except for belt stands). Developed for I, II, ..., V, Va site indexes, and ages from 20 to 140 years (Makarenko, 1980). The initial tables were developed over growth classes. Authors of the initial tables are A.A.Makarenko and A.I.Koltunova.

101212. Models for belt Pine stands (*lentochnie bory*) in steppe ecoregions of Siberia (A-XII). Developed for I, II, III, IV site indexes, and ages from 20 to 140 years (Makarenko, 1980). The initial tables were developed over growth classes. Authors of the initial tables are A.A.Makarenko and A.I.Koltunova.

4.2. Models for Modal Stands

101412. Models for western ecoregions of southern taiga and mixed forests of the European part, and recommended for Leningrad, Pskov and Novgorod oblasts. Developed for Ia, I, ..., V site indexes, and ages from 20 to 130 years. The models are developed as the aggregation of 7 different yield tables for modal stands of western regions of the former Soviet Union (including Baltic republic, Buyelorus, and the Russian North West), and from data of forest inventory and results of field measurements.

101412. Models for two groups of modal stands in Karelia and Murmanskaja oblast-with a relative stocking 0.65 and 0.8. Developed for I, ..., V, Va site indexes, and ages from 20 to 180 years. (Kozlov, 1985). Author of the initial tables is I.F.Kozlov.

101413. Models for the central ecoregions of the European part (southern taiga, mixed forests, deciduous forests, forest steppe). Developed for I, ..., V site indexes and covering an age-span from 20 to 140 years in the form of 6 aggregated yield tables for

modal stands of central and southern regions of Russia. Additional data have been used from Northern Ukraina and Buyelorus from forest inventory and from results of field measurements.

101412. Models for forest tundra and northern taiga ecoregions of the European North (excluding Karelia and Murmansk oblast), developed for IV, V, Va and Vb site indexes, and covering an age-span from 20 to 140 years (Voinov, 1986, Table 5.1.5, pp. 128-129). Author of the initial tables developed over forest types is B.A.Semenov. The total productivity was calculated based on data from field measurements.

101412. Models for mixed Pine stands with white birch and larch of northern taiga ecoregions of the West Siberian plain, developed for III, IV, ..., Vb site indexes and covering an age-span of 20 to 250 years (Falaleev et al., 1975, Table 58, pp 65-90). Author of the initial tables developed over forest types is A.E.Tetenkin.

101413. Models for Pine stands growing in hydromorphic conditions of northern, middle and southern taiga of Siberia. The models are developed as an aggregation of 3 different yield tables (developed over forest types) for IV, V, Va and Vb site indexes, and covering an age-span from 20 to 200 years (Smolnogov, 1970 and Falaleev et al., 1975).

101412. Models for Pine stands growing in automorphic conditions of northern, middle and southern taiga of Siberia. The models were developed as an aggregation of 4 different yield tables (developed over forest types) for III, IV, V and Va site indexes, and covers an age-span from 20 to 180 years (Smolnogov, 1970 and Falaleev et al., 1975).

Individual parameters of the models are presented in Tables 4 and 5. The tables calculated by the models are presented in Appendixes 1 and 2.

Digits in the code note:

first 3 digits - the type of the specie (101 - pine);
 4-th digit - the type of a table: 1 - normal general, 2 - normal regional, 3 - general (different stocking), 4 - modal;
 5-th digit - the type of age structure: 1 - unevenaged, 2 - moderately evenaged, 3 - evenaged, 4 - gradually evenaged;
 6th digit - the type of a serie: 1 - general, 2 - automorphic, 3 - hydromorphic.

5. Estimates on Increment and Mortality of Pine Stands in Russia

Two important indicators describing the current state and productivity of forests, gross growth (dTV) and net growth (dGS), were calculated based on the developed models for Russia. Data of Forest State Account-1993 (FSFMR, 1995) served as initial data (dominant species, age, site index, stocking, growing stock by ecoregions). The calculations were done based on percentages of gross and net growth derived from the system. Results of the calculations are presented in Appendix 3. Total gross and net growth of Pine forests in Russia were estimated to 388.4 to 200.1 million $m^3/year$ respectively. It means that the actual mortality is 188.3 million $m^3/year$. The average value for net growth of Pine in Russia is $1.60\ m^3/ha$ and year, but the European Pine forests have a current productivity of about two times higher than in Asia ($2.25\ m^3/ha$ and year versus $1.18\ m^3/ha$ and year). The main reasons for this difference are different climatic and soil conditions, more severe disturbance regimes in Asia, higher average age in the Asian part, and differences in the age structures of stands.

6. Conclusion

The models developed for Pine stands within the framework of a special modeling system can be used in many applications for ecological evaluations; for estimation of Net Primary Productivity (NPP) and Net Ecosystem Productivity (NEP) of the woody part of an ecosystem; for establishment of forest management practices; to substantiate the intensity of thinning; for forest inventory, etc. The models (within the framework of a complete MS) will be presented to the Federal Service of Forest Management of the Russian Federation for official consideration and future use in forest management of the country.
